Additional Reading	

The aim of this book is to provide you with a practical guide to web development using *Django 2* and *Python 3*. The book is designed primarily for students, providing a walkthrough of the steps involved in getting a web application up and running with Django.

This book seeks to complement the official Django Tutorials¹ and many of the other excellent tutorials available online. By putting everything together in one place, this book fills in many of the gaps in the official Django documentation providing an example-based design driven approach to learning the Django framework. Furthermore, this book provides an introduction to many of the aspects required to master web application development (e.g. HTML, CSS, JavaScript, etc.).

Why Work with this Book?

This book will save you time. On many occasions we've seen clever students get stuck, spending hours trying to fight with Django and other aspects of web development. More often than not, the problem was usually because a key piece of information was not provided, or something was not made clear. While the occasional blip might set you back 10-15 minutes, sometimes they can take hours to resolve. We've tried to remove as many of these hurdles as possible. This will mean you can get on with developing your application instead of stumbling along.

This book will lower the learning curve. Web application frameworks can save you a lot of hassle and lot of time. Well, that is if you know how to use them in the first place! Often the learning curve is steep. This book tries to get you going - and going fast by explaining how all the pieces fit together and how to build your web app in a logical manner.

This book will improve your workflow. Using web application frameworks requires you to pick up and run with particular design patterns - so you only have to fill in certain pieces in certain places. After working with many students, we heard lots of complaints about using web application frameworks - specifically about how they take control away from the software engineer (i.e. inversion of control²). To help you, we've created a number of *workflows* to focus your development process so that you can regain that sense of control and build your web application in a disciplined manner.

This book is not designed to be read. Whatever you do, *do not read this book!* It is a hands-on guide to building web applications in Django. Reading is not doing. To increase the value you gain from this experience, go through and develop the application. When you code up the application, *do not just cut and paste the code.* Type it in, think about what it does, then read the explanations

¹[tutorial01

²https://en.wikipedia.org/wiki/Inversion_of_control

we have provided. If you still do not understand, then check out the Django documentation, go to Stack Overflow³ or other helpful websites and fill in this gap in your knowledge. If you are really stuck, get in touch with us, so that we can improve the book - we've already had contributions from numerous other readers!

What you will Learn

In this book, we will be taking an exampled-based approach to web application development. In the process, we will show you how to design a web application called *Rango* (see the Design Brief below), and take a step by step in setting up, developing and deploying the application. Along the way, we'll show you how to perform the following key tasks which are common to most software engineering and web based projects.

- How to **setup your development environment** including how to use the terminal, your virtual environment, the pip installer, how to work with Git, and more.
- How to **setup a Django project** and create a basic Django application.
- How to **configure the Django project** to serve static media and other media files.
- How to work with Django's *Model-View-Template* design pattern.
- How to work with database models and use the *object relational mapping (ORM)*⁴ functionality provided by Django.
- How to **create forms** that can utilise your database models to create dynamically generated webpages.
- How to use the **user authentication** services provided by Django.
- How to incorporate external services into your Django application.
- How to include *Cascading Styling Sheets (CSS)* and *JavaScript* within a web application.
- How to apply CSS to give your application a professional look and feel.
- How to work with cookies and sessions with Django.
- How to include more advanced functionality like AJAX into your application.
- · How to write class based views
- How to **Deploy your application** to a web server using *PythonAnywhere*.

At the end of each chapter, we have also included a number of exercises designed to push you to apply what you have learnt during the chapter. Then to push you harder, we've included a number of open development challenges, which require you to use many of the lessons from the previous chapters - but don't worry we've also included solutions and explanations too!

³http://stackoverflow.com/questions/tagged/django

⁴https://en.wikipedia.org/wiki/Object-relational_mapping

Exercises will be clearly delineated like this!

In each chapter we have added a number of exercises to test your knowledge and skill.

You will need to complete these exercises as the subsequent chapters are dependent on them.

Don't worry if you get stuck, though, as you can always check out our solutions to all the exercises on our *GitHub* repository⁵.

⁵https://github.com/leifos/tango_with_django_2

Technologies and Services

Through the course of this book, we will used various technologies and external services including:

- the Python⁶ programming language;
- the Pip package manager⁷;
- Django⁸;
- the Git⁹ version control system;
- GitHub¹⁰;
- HTML¹¹;
- CSS¹²;
- the JavaScript¹³ programming language;
- the JQuery¹⁴ library;
- the Twitter Bootstrap¹⁵ framework;
- the Bing Search API16; and
- the PythonAnywhere¹⁷ hosting service;

We've selected these technologies and services as they are either fundamental to web development, and/or enable us to provide examples on how to integrate your web application with CSS toolkits like *Twitter Bootstrap*, external services like those provided by the *Webhose API* and deploy your application quickly and easily with *PythonAnywhere*. Ok, let's get started!

Rango: Initial Design and Specification

The focus of this book will be to develop an application called *Rango*. As we develop this application, it will cover the core components that need to be developed when building any web application. To see a fully functional version of the application, you can visit our How to Tango with Django website¹⁸.

Design Brief

Let's imagine that we would like to create a website called *Rango* that lets users browse through user-defined categories to access various web pages. In Spanish, the word rango¹⁹ is used to mean "a league ranked by quality" or "a position in a social hierarchy" - so we can imagine that at some point we will want to rank the web pages in Rango.

- For the **main page** of the Rango website, your client would like visitors to be able to see:
 - the *five most viewed pages*;
 - the five most viewed (or rango'ed) categories; and
 - *some way for visitors to browse or search* through categories.
- When a user views a category page, your client would like Rango to display:
 - the *category name, the number of visits, the number of likes*, along with the list of associated pages in that category (showing the page's title, and linking to its URL); and
 - *some search functionality (via the search API)* to find other pages that can be linked to this category.
- For a particular category, the client would like: the *name of the category to be recorded*; the *number of times each category page has been visited*; and how many users have *clicked a "like" button* (i.e. the page gets rango'ed, and voted up the social hierarchy).
- Each category should be accessible via a readable URL for example, /rango/books-about-django/.
- Only registered users will be able to search and add pages to categories. Visitors to the site should therefore be able to register for an account.

At first glance, the specified application to develop seems reasonably straightforward. In essence, it is just a list of categories that link to pages. However, there are a number of complexities and challenges that need to be addressed. First, let's try and build up a better picture of what needs to be developed by laying down some high-level designs.

¹⁸http://www.tangowithdjango.com/

¹⁹https://www.vocabulary.com/dictionary/es/rango

Exercises

Before going any further, think about these specifications and draw up the following design artefacts.

• What is the high level architecture going be? Draw up **N-Tier or System Architecture** diagram to represent the high level system components.

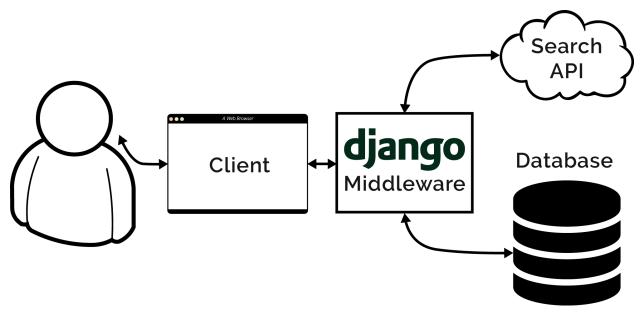

- What is the interface going to look like? Draw up some Wireframes of the main and category pages.
- What are the URLs that users visit going to look like? Write down a series of URL mappings for the application.
- What data are we going to have to store or represent? Construct an *Entity-Relationship* (*ER*)²⁰ diagram to describe the data model that we'll be implementing.

Try these exercises out before moving on - even if you aren't familiar with system architecture diagrams, wireframes or ER diagrams, how would you explain and describe, formally, what you are going to build so that someone else can understand it.

 $^{^{20}} https://en.wikipedia.org/wiki/Entity\%E2\%80\%93 relationship_model$

N-Tier Architecture

The high-level architecture for most web applications is based around a *3-Tier architecture*. Rango will be a variant on this architecture as also interfaces with an external service.

Overview of the 3-tier system architecture for our Rango application.

Given the different boxes within the high level architecture, we need to start making some decisions about the technologies that will be going into each box. Since we are building a web application with Django, we will use the following technologies for the following tiers.

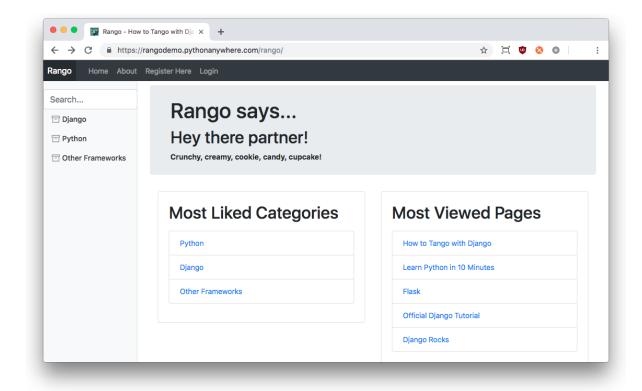

- The **client** will be a Web browser (such as *Chrome*, *Firefox*, and *Safari*) which will render HTML/CSS pages.
- The **middleware** will be a *Django* application, and will be dispatched through Django's builtin development Web server while we develop (and then later a web server like *nginx* or *apache web server*).
- The **database** will be the Python-based *SQLite3* Database engine.
- The **search API** will be the search API.

For the most part, this book will focus on developing the middleware. It should however be quite evident from the system architecture diagram that we will have to interface with all the other components.

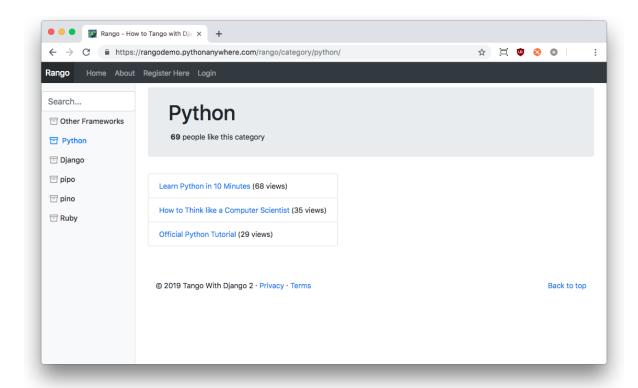

Wireframes

Wireframes are great way to provide clients with some idea of what the application is going to look like and what features it will provide. They save a lot of time, and can vary from hand drawn sketches

to exact mockups depending on the tools that you have at your disposal. For our Rango application, we'd like to make the index page of the site look like the screenshot below. Our category page is also shown below.

The index page with a categories search bar on the left, also showing the top five pages and top five categories.

The category page showing the pages in the category (along with the number of views for the category and each page).

Pages and URL Mappings

From the specification, we have already identified two pages that our application will present to the user at different points in time. To access each page we will need to describe URL mappings. Think of a URL mapping as the text a user would have to enter into a browser's address bar to reach the given page. The basic URL mappings for Rango are shown below.

- / or /rango/ will point to the main / index page.
- /rango/about/ will point to the about page.
- /rango/category/<category_name>/ will point to the category page for <category_name>, where the category might be:
 - games;
 - python-recipes; or
 - code-and-compilers.

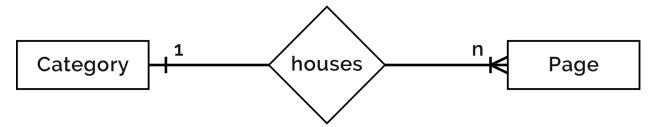

As we build our application, we will probably need to create other URL mappings. However, the ones listed above will get us started and give us an idea of the different pages. Also, as we progress through the book, we will flesh out how to construct these pages using the Django framework and use its Model-View-Template²¹ design pattern. However, now that we have a gist of the URL mappings and

²¹[django2]

what the pages are going to look like, we need to define the data model that will house the data for our Web application.

Entity-Relationship Diagram

Given the specification, it should be clear that we have at least two entities: a *category* and a *page*. It should also be clear that a *category* can house many *pages*. We can formulate the following ER Diagram to describe this simple data model.

The Entity Relationship Diagram of Rango's two main entities.

Note that this specification is rather vague. A single page could in theory exist in one or more categories. Working with this assumption, we could model the relationship between categories and pages as a many-to-many relationship²². This approach however introduces a number of complexities, so we will make the simplifying assumption that *one category contains many pages*, but one page is assigned to one category. This does not preclude that the same page can be assigned to different categories - but the page would have to be entered twice. While this is not ideal, it does reduce the complexity of the models.

Take Note!

Get into the habit of noting down any working assumptions that you make, just like the one-to-many relationship assumption that we assume above. You never know when they may come back to bite you later on! By noting them down, this means you can communicate it with your development team and make sure that the assumption is sensible and that they are happy to proceed under such an assumption.

With this assumption, we can produce a series of tables that describe each entity in more detail. The tables contain information on what fields are contained within each entity. We use Django ModelField types to define the type of each field (i.e. IntegerField, CharField, URLField or ForeignKey). Note that in Django *primary keys* are implicit such that Django adds an id to each Model, but we will talk more about that later in the Models and Database chapter.

Category Model

²²https://en.wikipedia.org/wiki/Many-to-many_(data_model)

Field	Туре
name	CharField
views	IntegerField
likes	IntegerField

Page Model

Field	Туре	
category	ForeignKey	
title	CharField	
url	URLField	
views	IntegerField	

We will also have a model for the User so that they can register and login. We have not shown it here, but shall introduce it later in the book when we discuss User Authentication. In the following chapters, will we see how to instantiate these models in Django and how to use the built-in ORM to connect to the database.

Summary

These high level design and specifications will serve as a useful reference point when building our Web application. While we will be focusing on using specific technologies, these steps are common to most database driven websites. It's a good idea to become familiar with reading and producing such specifications and designs so that you can communicate your designs and ideas with others. Here we will be focusing on using Django and the related technologies to implement this specification.

Cut and Paste Coding

As you progress through the tutorial, you'll most likely be tempted to cut and paste the code from the book to your code editor. **However**, it is better to type in the code. We know that this is a hassle, but it will help you to remember the process and get a feel for the commands that you will be using again and again.

Furthermore, cutting and pasting Python code is asking for trouble. Whitespace can end up being interpreted as spaces, tabs or a mixture of spaces and tabs. This will lead to all sorts of weird errors, and not necessarily indent errors. If you do cut and paste code be wary of this. Pay particular attention to this if you're using Python 3 - inconsistent use of tabs and spaces in your code's indentation will lead to a TabError.

Most code editors will show the whitespace and whether it is tabs or spaces. If so, turn it on and save yourself a lot of confusion.

Representing Commands

As you work through this book, you'll encounter lots of text that will be entered into your computer's terminal or Command Prompt. Snippets starting with a dollar sign (\$) denotes a command that must be entered – the remainder of the line is the command. In a UNIX terminal, the dollar represents a separator between the *prompt* and the command that you enter.

david@seram:~ \$ exit

In the example above, the prompt <code>david@seram</code>: \sim tells us our username (<code>david</code>), computer name (<code>seram</code>) and our current directory (\sim , or our home directory). After the \$, we have entered the command <code>exit</code>, which, when executed, will close the terminal. Refer to the UNIX chapter for more information.

Before we start coding, it's really important that we set your development environment up correctly so that you can *Tango with Django* easily. You'll need to make sure that you have all of the necessary components installed on your computer, and that they are configured correctly. This chapter outlines the six key components you'll need to be aware of, setup and use. These are:

- the terminal²³ (on macOS or UNIX/Linux systems), or the Command Prompt²⁴ (on Windows);
- Python 3, including how to code and run Python scripts;
- the Python Package Manager pip;
- Virtual Environments;
- your Integrated Development Environment (IDE), if you choose to use one; and
- a Version Control System (VCS) called Git.

If you already have Python 3 and Django 2 installed on your computer and are familiar with the technologies listed above, you can skip straight ahead to the Django Basics chapter. If you are not familiar with some or all of the technologies listed, we provide an overview of each below. These go hand in hand with later supplementary chapter that provide a series of pointers on how to set the different components up, if you need help doing so.

You Development Environment is Important!

Setting up your development environment can be a tedious and frustrating process. It's not something that you would do everyday. The pointers we provide in this chapter (and the additional supplementary chapter) should help you in getting everything to a working state. The effort you expend now in making sure everything works will ensure that development can proceed unhindered.

From experience, we can also say with confidence that as you set your environment up it's a good idea to note down the steps that you took. You will probably need that workflow again one day – maybe you will purchase a new computer, or be asked to help a friend set their environment up, too. *Don't think short-term, think long-term!*

Python 3

To work with Tango with Django, we require you to have installed on your computer a copy of the *Python 3* programming language. A Python version of 3.4 or greater should work fine with Django

²³https://en.wikipedia.org/wiki/Terminal_emulator

²⁴https://en.wikipedia.org/wiki/Cmd.exe

2.1 – although the official Django website recommends that you have the most recent version of Python installed. As such, we recommend you install *Python 3.7*. At the time of writing, the most recent release is *Python 3.7.2*. If you're not sure how to install Python and would like some assistance, have a look at our quick guide on how to install Python.

Running macOS, Linux or UNIX?

On installations of macOS, Linux or UNIX, you will find that Python is already installed on your computer – albeit a much older version, typically 2.x. This version is required by your operating system to perform essential tasks such as downloading and installing updates. While you can use this version, it most likely won't be compatiable with Django 2, and you'll need to install a newer version of Python to run *side-by-side* with the old installation. *Do not uninstall Python 2.x* if it is already present on your system; you may break your operating system!

Python Skills Rusty?

If you haven't used Python before – or you simply want to brush up on you skills – then we highly recommend that you check out and work through one or more of the following guides:

- The Official Python Tutorial²⁵;
- Think Python: How to Think like a Computer Scientist²⁶ by Allen B. Downey; or
- Learn Python in 10 Minutes²⁷ by Stavros;
- Learn to Program²⁸ by Jennifer Campbell and Paul Gries.

These guides will help you familiarise yourself with the basics of Python so you can start developing with Django. Note you don't need to be an expert in Python to work with Django – Python is straightforward to use, and you can pick it up as you go, especially if you already know another programming language.

Virtual Environments

With a working installation of Python 3 (and the basic programming skills to go with it), we can now setup our environment for the Django project (called Rango) we'll be creating in this tutorial. One super useful tool we *strongly* encourage you to use is a virtual environment. Although not strictly necessary, it provides a useful separation between your computer's Python installation and the environment you'll be using to develop Rango with.

²⁵http://docs.python.org/3/tutorial/

²⁶http://www.greenteapress.com/thinkpython/

²⁷http://www.korokithakis.net/tutorials/python/

²⁸https://www.coursera.org/course/programming1

A virtual environment allows for multiple installations of Python packages to exist in harmony, within unique *Python environments*. Why is this useful? Say you have a project, projectA that you want to run in Django 1.11, and a further project, projectB written for Django 2.1. This presents a problem as you would normally only be able to install one version of the required software at a time. By creating virtual environments for each project, you can then install the respective versions of Django (and any other required Python software) within each unique environment. This ensures that the software installed in one environment does not tamper with the software installed on another.

You'll want to create a virtual environment using Python 3 for your Rango development environment. Call the environment rangoenv. If you are unsure as to how to do this, go to the supplementary chapter detailing how to set up virtual environments before continuing. If you do choose to use a virtual environment, remember to activate the virtual environment by issuing the following command.

```
$ workon rangoenv
```

From then on, all of your prompts with the Terminal or Command Prompt will precede with the name of your virtual environment to remind you that it is switched on. Check out the following example to know what we are discussing.

```
$ workon rangoenv
(rangoenv) $ pip install django==2.1.5
...
(rangoenv) $ deactivate
```

The penultimate line of the example above demonstrates how to switch your virtual environment off after you have finished with it – note the lack of (rangoenv) before the prompt. Again, refer to the later chapter in this tutorial for more information on how to setup and use virtual environments.

The Python Package Manager

Going hand in hand with virtual environments, we'll also be making use of the Python package manager, *pip*, to install a number of different Python software packages – including Django – to our development environment. Specifically, we'll need to install two packages: Django 2.1.5 and *Pillow*. Pillow is a Python package providing support for handling image files (e.g. . jpg and .png files), something we'll be doing later in this tutorial.

A package manager, whether for Python, your operating system²⁹ or some other environment³⁰, is a software tool that automates the process of installing, upgrading, configuring and removing

²⁹https://en.wikipedia.org/wiki/Advanced_Packaging_Tool

³⁰https://docs.npmjs.com/cli/install

packages – that is, a package of software which you can use on your computer. This is opposed to downloading, installing and maintaining software manually. Maintaining Python packages is pretty painful. Most packages often have *dependencies* – additional packages that are required for your package to work! This can get very complex very quickly. A package manager handles all of this for you, along with issues such as conflicts regarding different versions of a package. Luckily, *pip* handles all this for you – so you can sit back and relax.

Try and run the command \$ pip3 for the Python 3 version of the package manager. If that doesn't work, you have a setup issue – refer to our pip setup guide for help.

With your virtual environment switched on, execute the following two commands to install Django and Pillow.

```
$ pip install django==2.1.5
$ pip install pillow==5.0.0
```

This will be enough to get you started. As you work through the tutorial, there will be a couple more packages that we will require. These will be installed as we require them. For now, you're good to go.

Problems Installing pillow?

When installing Pillow, you may receive an error stating that the installation failed due to a lack of JPEG support. This error is shown as the following:

```
ValueError: jpeg is required unless explicitly disabled using --disable-jpeg, aborting
```

If you receive this error, try installing Pillow without JPEG support enabled, with the following command.

While you obviously will have a lack of support for handling JPEG images, Pillow should then install without problem. Getting Pillow installed is enough for you to get started with this tutorial. For further information, check out the Pillow documentation³¹.

Working within in a Virtual Environment

Substitute pip3 with pip when working within your virtual environment. The command pip is aliased to the correct one for your virtual environment.

 $^{^{\}bf 31} https://pillow.readthedocs.io/en/stable/installation.html$

Integrated Development Environment

While not absolutely necessary, a good Python-based IDE can be very helpful to you during the development process. Several exist, with perhaps *PyCharm*³² by JetBrains and *PyDev* (a plugin of the Eclipse IDE³³) standing out as popular choices. The Python Wiki³⁴ provides an up-to-date list of Python IDEs.

Research which one is right for you, and be aware that some may require you to purchase a licence. Ideally, you'll want to select an IDE that supports integration with Django. Of course, if you prefer not to use an IDE, using a simple text editor like Sublime Text³⁵, TextMate³⁶ or Atom³⁷ will do just fine. Many modern text editors actually support Python syntax highlighting, which makes things much easier!

We use PyCharm as it supports virtual environments and Django integration – though you will have to configure the IDE accordingly. We don't cover that here - although JetBrains do provide a guide on setting PyCharm up³⁸.

Version Control System

We should also point out that when you develop code, you should always house your code within a version-controlled repository such as SVN³⁹ or Git⁴⁰. We won't be explaining this right now, so that we can get stuck into developing an application in Django. We have however written a chapter providing a crash course on Git for your reference that you can refer to later on. We highly recommend that you set up a Git repository for your own projects.

Exercises

To get comfortable with your environment, try out the following exercises.

• Get up to speed with Python if you're new to the language. Try out one or more of the tutorials we list earlier.

- Install Python 3.7. Make sure pip3 (or pip with your virtual environment) is also installed and works on your computer.
- Play around with your *command line interface (CLI)*, whether it be the Command Prompt (Windows) or a Terminal (macOS, Linux, UNIX, etc.) and create a directory called code, which we use to create our projects in.
- Create a new virtual environment using Python 3.7. This is optional; but we *strongly encourage you to use virtual environments*.
- Within your environment, install Django 2.1.5 and Pillow 5.0.0.
- Setup an account on a Git repository site like GitHub⁴¹ or BitBucket⁴² if you haven't already done so.
- Download and setup an IDE like PyCharm⁴³, or setup your favourite text editor for working with Python files.

As previously stated, we've made the code for the book and application available on our GitHub repository⁴⁴.

- If you spot any errors or problems, please let us know by making a change request on GitHub.
- If you have any problems with the exercises, you can check out the repository to see how we completed them.

What is a Directory?

In the text above, we refer to creating a *directory*. But what exactly is a *directory*? If you have used a Windows computer up until now, you'll know a directory as a *folder*. The concept of a folder is analogous to a directory – it is a cataloguing structure that contains references to other files and directories.

Once you've worked through all of these exercises, you'll be a competent Python programmer – and will have a computer that is set up and ready to *Tango with Django!*

⁴¹https://github.com/

⁴²https://bitbucket.org/

⁴³https://www.jetbrains.com/pycharm/

⁴⁴https://github.com/leifos/tango_with_django_2/

Let's get started with Django! In this chapter, we'll be giving you an overview of the creation process. You'll be setting up a new project and a new Web application. By the end of this chapter, you will have a simple Django powered website up and running!

Testing Your Setup

Let's start by checking that your Python and Django installations are correct for this tutorial. To do this, open a new terminal window, and enter your virtual environment.

Then issue the following command, which tells you what Python version you have.

```
$ python --version
```

The response should be something like 3.5.5 or 3.5.1, but any 3.4+ versions of Python should work fine. If you need to upgrade or install Python go to the chapter on setting up your system.

If you are using a virtual environment, then ensure that you have activated it - if you don't remember how, then go to our chapter on virtual environments.

After verifying your Python installation, check your Django installation. In your terminal window, run the Python interpreter by issuing the following command.

```
$ python
Python 3.6.3 (default, Oct 4 2017, 06:09:38)
[GCC 4.2.1 Compatible Apple LLVM 9.0.0 (clang-900.0.37)] on darwin
Type "help", "copyright", "credits" or "license" for more information.
>>>
```

At the prompt, enter the following commands:

```
>>> import django
>>> django.get_version()
'2.0.2'
>>> exit()
```

All going well you should see the correct version of Django, and then can use exit() to leave the Python interpreter. If import django fails to import, then check that you are in your virtual environment, and check what packages are installed with pip list at the terminal window.

If you have problems with installing the packages or have a different version installed, go to System Setup chapter or consult the Django Documentation on Installing Django⁴⁵.

Prompts

In this book, there's two things you should look out for when we include code snippets.

Snippets beginning with a dollar sign (\$) indicates that the remainder of the following line is a terminal or Command Prompt command. We mentioned this in the first chapter, but it's worth repeating so you are sure what this notation represents.

Whenever you see >>>, the following is a command that should be entered into the interactive Python interpreter. This is launched by issuing \$ python. See what we did there? You can also exit the Python interpreter by entering quit() or exit().

Creating Your Django Project

To create a new Django Project, go to your workspace directory, and issue the following command:

\$ django-admin.py startproject tango_with_django_project

If you don't have a workspace directory, then create one, so that you can house your Django projects and other code projects within this directory. We will refer to your workspace directory in the code as <workspace>. You will have to substitute in the path to your workspace directory, for example: /Users/leifos/Code/ or /Users/maxwelld90/Workspace/.

Can't find django-admin.py?

Try entering django-admin instead. Depending on your setup, some systems may not recognise django-admin.py.

While, on Windows, you may have to use the full path to the django-admin.py script, for example:

 $\label{lem:c:python27} $$\operatorname{c:python27\scripts\django-admin.py} $$\operatorname{startproject\ tango_with_django_project}$$$

as suggested on StackOverflow⁴⁶.

⁴⁵https://docs.djangoproject.com/en/1.9/topics/install/

 $^{{}^{46}} http://stackoverflow.com/questions/8112630/cant-create-django-project-using-command-prompt}$

This command will invoke the django-admin.py script, which will set up a new Django project called tango_with_django_project for you. Typically, we append _project to the end of our Django project directories so we know exactly what they contain - but the naming convention is entirely up to you.

You'll now notice within your workspace is a directory set to the name of your new project, tango_with_django_project. Within this newly created directory, you should see two items:

- another directory with the same name as your project, tango_with_django_project; and
- a Python script called manage.py.

For the purposes of this tutorial, we call this nested directory called tango_with_django_project the *project configuration directory*. Within this directory, you will find four Python scripts. We will discuss these scripts in detail later on, but for now you should see:

- __init__.py, a blank Python script whose presence indicates to the Python interpreter that the directory is a Python package;
- settings.py, the place to store all of your Django project's settings;
- urls.py, a Python script to store URL patterns for your project; and
- wsgi.py, a Python script used to help run your development server and deploy your project to a production environment.

In the project directory, you will see there is a file called <code>manage.py</code>. We will be calling this script time and time again as we develop our project. It provides you with a series of commands you can run to maintain your Django project. For example, <code>manage.py</code> allows you to run the built-in Django development server, test your application and run various database commands. We will be using the script for virtually every Django command we want to run.

The Django Admin and Manage Scripts

For Further Information on Django admin script, see the Django documentation for more details about the Admin and Manage scripts⁴⁷.

Note that if you run python manage.py help you can see the list of commands available.

You can try using the manage py script now, by issuing the following command.

\$ python manage.py runserver

Executing this command will launch Python, and instruct Django to initiate its lightweight development server. You should see the output in your terminal window similar to the example shown below:

⁴⁷https://docs.djangoproject.com/en/1.9/ref/django-admin/#django-admin-py-and-manage-py

```
$ python manage.py runserver

Performing system checks...

System check identified no issues (0 silenced).

You have 14 unapplied migration(s).

Your project may not work properly until you apply the migrations for app(s): admin, auth, contenttypes, sessions.

Run 'python manage.py migrate' to apply them.

February 20, 2018 - 03:46:44

Django version 2.0.2, using settings 'tango_with_django_project.settings'

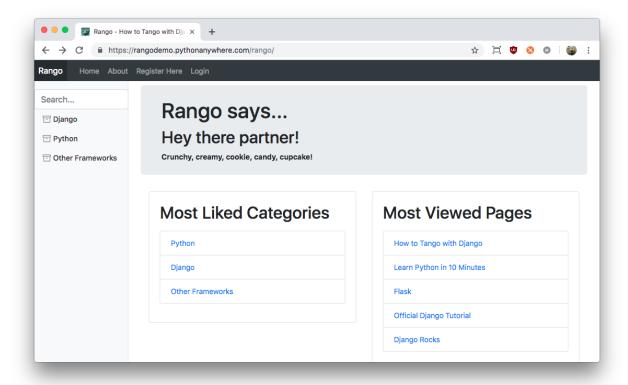

Starting development server at http://127.0.0.1:8000/

Quit the server with CONTROL-C.
```

In the output you can see a number of things. First, there are no issues that stop the application from running. Second, however, you will notice that a warning is raised, i.e. unapplied migrations. We will talk about this in more detail when we setup our database, but for now we can ignore it. Third, and most importantly, you can see that a URL has been specified: http://127.0.0.1:8000/, which is the address of the Django development webserver.

Now open up your Web browser and enter the URL http://127.0.0.1:8000/48. You should see a webpage similar to the one shown in below.

⁴⁸http://127.0.0.1:8000/

A screenshot of the initial Django page you will see when running the development server for the first time.

You can stop the development server at anytime by pushing CTRL + C in your terminal or Command Prompt window. If you wish to run the development server on a different port, or allow users from other machines to access it, you can do so by supplying optional arguments. Consider the following command:

\$ python manage.py runserver <your_machines_ip_address>:5555

Executing this command will force the development server to respond to incoming requests on TCP port 5555. You will need to replace <your_machines_ip_address> with your computer's IP address or 127.0.0.1.

Don't know your IP Address?

If you use 0.0.0.0, Django figures out what your IP address is. Go ahead and try:

python manage.py runserver 0.0.0.0:5555

When setting ports, it is unlikely that you will be able to use TCP port 80 or 8080 as these are traditionally reserved for HTTP traffic. Also, any port below 1024 is considered to be privileged⁴⁹ by your operating system.

 $^{^{\}bf 49} http://www.w3.org/Daemon/User/Installation/PrivilegedPorts.html$

While you won't be using the lightweight development server to deploy your application, it's nice to be able to demo your application on another machine in your network. Running the server with your machine's IP address will enable others to enter in http://<your_machines_ip_address>:<port>/ and view your Web application. Of course, this will depend on how your network is configured. There may be proxy servers or firewalls in the way that would need to be configured before this would work. Check with the administrator of the network you are using if you can't view the development server remotely.

Creating a Django App

A Django project is a collection of *configurations* and *apps* that together make up a given Web application or website. One of the intended outcomes of using this approach is to promote good software engineering practices. By developing a series of small applications, the idea is that you can theoretically drop an existing application into a different Django project and have it working with minimal effort.

A Django application exists to perform a particular task. You need to create specific apps that are responsible for providing your site with particular kinds of functionality. For example, we could imagine that a project might consist of several apps including a polling app, a registration app, and a specific content related app. In another project, we may wish to re-use the polling and registration apps, and so can include them in other projects. We will talk about this later. For now we are going to create the app for the *Rango* app.

To do this, from within your Django project directory (e.g. workspace>/tango_with_django_project), run the following command.

\$ python manage.py startapp rango

The startapp command creates a new directory within your project's root. Unsurprisingly, this directory is called rango - and contained within it are a number of Python scripts:

- another __init__.py, serving the exact same purpose as discussed previously;
- admin.py, where you can register your models so that you can benefit from some Django machinery which creates an admin interface for you;
- apps.py, that provides a place for any app specific configuration;
- models.py, a place to store your app's data models where you specify the entities and relationships between data;
- tests.py, where you can store a series of functions to test your app's code;
- views.py, where you can store a series of functions that handle requests and return responses; and
- migrations directory, which stores database specific information related to your models.

views.py and models.py are the two files you will use for any given app, and form part of the main architectural design pattern employed by Django, i.e. the *Model-View-Template* pattern. You can check out the official Django documentation⁵⁰ to see how models, views and templates relate to each other in more detail.

Before you can get started with creating your own models and views, you must first tell your Django project about your new app's existence. To do this, you need to modify the settings.py file, contained within your project's configuration directory. Open the file and find the INSTALLED_APPS tuple. Add the rango app to the end of the tuple, which should then look like the following example.

```
INSTALLED_APPS = [
   'django.contrib.admin',
   'django.contrib.auth',
   'django.contrib.contenttypes',
   'django.contrib.sessions',
   'django.contrib.messages',
   'django.contrib.staticfiles',
   'rango',
]
```

Verify that Django picked up your new app by running the development server again. If you can start the server without errors, your app was picked up and you will be ready to proceed to the next step.

startapp Magic

When creating a new app with the python manage.py startapp command, Django may add the new app's name to your settings.py INSTALLED_APPS list automatically for you. It's nevertheless good practice to check everything is setup correctly before you proceed.

Creating a View

With our Rango app created, let's now create a simple view. Views handle a request, and provide a response. In order to fulfil the request it may contact other services or query for data from other sources. The views job is to collate and package the data required to handle the request. For our first view, given a request, the view will simply send some text back to the client. For the time being we won't concern ourselves about using models (i.e. getting data from other sources) or templates (i.e. which help us package our data nicely).

In your favourite IDE, open the file views.py, located within your newly created rango app directory. Remove the comment # Create your views here. so that you now have a blank file.

You can now add in the following code.

⁵⁰https://docs.djangoproject.com/en/1.2/intro/overview/

```
from django.http import HttpResponse

def index(request):
    return HttpResponse("Rango says hey there partner!")
```

Breaking down the three lines of code, we observe the following points about creating this simple view.

- We first import the HttpResponse⁵¹ object from the django.http module.
- Each view exists within the views.py file as a series of individual functions. In this instance, we only created one view called index.
- Each view takes in at least one argument a HttpRequest⁵² object, which also lives in the django.http module. Convention dictates that this is named request, but you can rename this to whatever you want if you so desire.
- Each view must return a HttpResponse object. A simple HttpResponse object takes a string parameter representing the content of the page we wish to send to the client requesting the view.

With the view created, you're only part of the way to allowing a user to access it. For a user to see your view, you must map a Uniform Resource Locator (URL)⁵³ to the view.

To create an initial mapping, open urls.py located in your project directory and add the following lines of code to the urlpatterns:

```
from rango import views

urlpatterns = [
   path('', views.index, name='index'),
   path('admin/', admin.site.urls),
]
```

This maps the basic URL to the index view in the rango app. Run the development server (e.g. python manage.py runserver) and visit http://127.0.0.1:8000 or whatever address your development server is running on. You'll then see the rendered output of the index view.

Mapping URLs

Rather than directly mapping URLs from the project to the app, we can make our app more modular (and thus re-usable) by changing how we route the incoming URL to a view. To do this, we first

 $^{^{52}} https://docs.djangoproject.com/en/1.9/ref/request-response/\#django.http.HttpRequest-response/\#django.http.HttpRequest-response/\#django.http.HttpRequest-response/\#django.http.HttpRequest-response/\#django.http.HttpRequest-response/\#django.http.HttpRequest-response/#django$

⁵³http://en.wikipedia.org/wiki/Uniform_resource_locator

need to modify the project's urls.py and have it point to the app to handle any specific Rango app requests. We then need to specify how Rango deals with such requests.

First, open the project's urls.py file which is located inside your project configuration directory. As a relative path from your workspace directory, this would be the file <workspace>/tango_with_django_project/urls.py. Update the urlpatterns list as shown in the example below.

You will see that the urlpatterns is a Python list, which is expected by the Django framework. The added mapping looks for URL strings that match the patterns rango/. When a match is made the remainder of the URL string is then passed onto and handled by rango urls through the use of the include() function from within django.conf.urls.

Think of this as a chain that processes the URL string - as illustrated in the URL chain figure. In this chain, the domain is stripped out and the remainder of the URL string (rango/) is passed on to tango_with_django project, where it finds a match and strips away rango/, leaving an empty string to be passed on to the app rango for it to handle.

Consequently, we need to create a new file called urls.py in the rango app directory, to handle the remaining URL string (and map the empty string to the index view):

```
from django.urls import path
from rango import views

urlpatterns = [
    path('', views.index, name='index'),
]
```

This code imports the relevant Django machinery for URL mappings and the views module from rango. This allows us to call the function url and point to the index view for the mapping in urlpatterns.

When we talk about URL strings, we assume that the host portion of a given URL has *already been stripped away*. The host portion of a URL denotes the host address or domain name that maps to the webserver, such as http://127.0.0.1:8000 or http://www.tangowithdjango.com. Stripping the host portion away means that the Django machinery needs to only handle the remainder of the URL string. For example, given the URL http://127.0.0.1:8000/rango/about/, Django will handle the /rango/about/ part of the URL string.

The URL mapping we have created above calls Django's path() function, where the first parameter is the string to match. In this case, as we have used an empty string '', then Django will only find a match if there is nothing after http://127.0.0.1:8000/. The second parameter tells Django what view to call if the pattern '' is matched. In this case, views.index() will be called. The third, and optional, parameter is called name. It provides a convienent way to reference the view, and by naming our URL mappings we can employ reverse URL matching. That is we can reference the URL mapping by name rather than by the URL. Later we will explain and show why this is incredibly useful - saving you time and hassle as your application become more complex.

Now, restart the Django development server and visit http://127.0.0.1:8000/rango/. If all went well, you should see the text Rango says hey there partner!. It should look just like the screenshot shown below.

An illustration of a URL, represented as a chain, showing how different parts of the URL following the domain are the responsibility of different url.py files.

A screenshot of a Web browser displaying our first Django powered webpage. Hello, Rango!

Within each app, you will create a number of URL mappings. The initial mapping is quite simple, but as we progress through the book we will create more sophisticated, parameterised URL mappings.

It's also important to have a good understanding of how URLs are handled in Django. It may seem a bit confusing right now, but as we progress through the book, we will be creating more and more URL mappings, so you'll soon be a pro. To find out more about them, check out the official Django documentation on URLs⁵⁴ for further details and further examples.

⁵⁴https://docs.djangoproject.com/en/2.0/topics/http/urls/

Note on Regular Expressions

Django URL patterns use regular expressions⁵⁵ to perform the matching. It is worthwhile familiarising yourself on how to use regular expressions in Python. The official Python documentation contains a useful guide on regular expressions⁵⁶, while regexcheatsheet.com provides a neat summary of regular expressions⁵⁷.

If you are using version control, now is a good time to commit the changes you have made to your workspace. Refer to the chapter providing a crash course on Git if you can't remember the commands and steps involved in doing this.

Basic Workflows

What you've just learnt in this chapter can be succinctly summarised into a list of actions. Here, we provide these lists for the two distinct tasks you have performed. You can use this section for a quick reference if you need to remind yourself about particular actions later on.

Creating a new Django Project

1. To create the project run, python django-admin.py startproject <name>, where <name> is the name of the project you wish to create.

Creating a new Django App

- 1. To create a new app, run \$ python manage.py startapp <appname>, where <appname> is the name of the app you wish to create.
- 2. Tell your Django project about the new app by adding it to the INSTALLED_APPS tuple in your project's settings.py file.
- 3. In your project urls.py file, add a mapping to the app.
- 4. In your app's directory, create a urls.py file to direct incoming URL strings to views.
- 5. In your app's view.py, create the required views ensuring that they return a HttpResponse object.

⁵⁵http://en.wikipedia.org/wiki/Regular_expression

⁵⁶http://docs.python.org/2/howto/regex.html

⁵⁷http://regexcheatsheet.com/

Django Basics 30

Exercises

Now that you have got Django and your new app up and running, give the following exercises a go to reinforce what you've learnt. Getting to this stage is a significant landmark in working with Django. Creating views and mapping URLs to views is the first step towards developing more complex and usable Web applications.

- Revise the procedure and make sure you follow how the URLs are mapped to views.
- Create a new view method called about which returns the following HttpResponse: 'Rango says here is the about page.'
- Map this view to /rango/about/. For this step, you'll only need to edit the urls.py of the Rango app. Remember the /rango/ part is handled by the projects urls.py.
- Revise the HttpResponse in the index view to include a link to the about page.
- In the HttpResponse in the about view include a link back to the main page.
- Now that you have started the book, follow us on Twitter @tangowithdjango⁵⁸, and let us know how you are getting on!

Hints

If you're struggling to get the exercises done, the following hints will hopefully provide you with some inspiration on how to progress.

- In your views.py, create a function called: def about(request):, and have the function return a HttpResponse(), insert your HTML inside this response.
- The expression to use for matching is 'about/' so in rango/urls.py add in a new path mapping to the about() view.
- Update your index() view to include a link to the about view. Keep it simple for now something like Rango says hey there partner!

 '> ca href='/rango/about/'>About.
- Also add the HTML to link back to the index page is into your response from the about() view Index.
- If you haven't done so already, now's a good time to head off and complete part one of the official Django Tutorial⁵⁹.

⁵⁸https://twitter.com/tangowithdjango

⁵⁹https://docs.djangoproject.com/en/2.0/intro/tutorial01/

In this chapter, we'll be introducing the Django template engine, as well as showing how to serve both *static* files and *media* files. Rather than crafting each page, we can use templates to provide the skeleton structure of the page, and then in the view we can provide the template with the neccessary data to render that page. To incorporate javascript and css, along with images and other media content, we will use the machinery provided by Django to include and dispath such files to provide added functionality (in the case of javascript) or to provide styles to our pages.

Using Templates

Up until this point, we have only connected a URL mapping to a view. The Django framework, however, is based around the *Model-View-Template* architecture. In this section, we will go through the mechanics of how *Templates* work with *Views*, then in the next couple of chapters we will put these together with *Models*.

Why templates? The layout from page to page within a website is often the same. Whether you see a common header or footer on a website's pages, the repetition of page layouts⁶⁰ aids users with navigation, promotes organisation of the website and reinforces a sense of continuity. Django provides templates⁶¹ to make it easier for developers to achieve this design goal, as well as separating application logic (code within your views) from presentational concerns (look and feel of your app). In this chapter, you'll create a basic template that will be used to create a HTML page. This template will then be dispatched via a Django view. In the chapter concerning databases and models, we will take this a step further by using templates in conjunction with models to dispatch dynamically generated data.

Summary: What is a Template?

In the world of Django, think of a *template* as the scaffolding that is required to build a complete HTML webpage. A template contains the *static parts* of a webpage (that is, parts that never change), complete with special syntax (or *template tags*) which can be overridden and replaced with *dynamic content* that your Django app's views can replace to produce a final HTML response.

⁶⁰http://www.techrepublic.com/blog/web-designer/effective-design-principles-for-web-designers-repetition/

⁶¹https://docs.djangoproject.com/en/1.2/ref/templates/

Configuring the Templates Directory

To get templates up and running with your Django app, you'll need to create two directories in which template files are stored.

In your Django project's directory (e.g. workspace>/tango_with_django_project/), create a new directory called templates. Remember, this is the directory that contains your project's manage.py script! Within the new templates directory, create another directory called rango. This means that the path workspace>/tango_with_django_project/templates/rango/ will be the location in which we will store templates associated with our rango application.

Keep your Templates Organised

It's good practice to separate out your templates into subdirectories for each app you have. This is why we've created a rango directory within our templates directory. If you package your app up to distribute to other developers, it'll be much easier to know which templates belong to which app!

To tell the Django project where templates will be stored, open your project's settings.py file. Next, locate the TEMPLATES data structure. By default, when you create a new Django project, it will look like the following.

What we need to do to is tell Django where our templates will be stored by modifying the DIRS list, which is set to an empty list by default. Change the dictionary key/value pair to look like the following.

```
'DIRS': ['<workspace>/tango_with_django_project/templates']
```

Note that you are *required to use absolute paths* to locate the templates directory. If you are collaborating with team members or working on different computers, then this will become a problem. You'll have different usernames and different drive structures, meaning the paths to the <workspace> directory will be different. One solution would be to add the path for each different configuration. For example:

However, there are a number of problems with this. First you have to add in the path for each setting, each time. Second, if you are running the app on different operating systems the backslashes have to be constructed differently.

Don't hard code Paths!

The road to hell is paved with hard coded paths. Hard-coding paths⁶² is a software engineering anti-pattern⁶³, and will make your project less portable⁶⁴ - meaning that when you run it on another computer, it probably won't work!

Dynamic Paths

A better solution is to make use of built-in Python functions to work out the path of your templates directory automatically. This way, an absolute path can be obtained regardless of where you place your Django project's code. This in turn means that your project becomes more *portable*.

At the top of your settings.py file, there is a variable called BASE_DIR. This variable stores the path to the directory in which your project's settings.py module is contained. This is obtained by using the special Python __file__ attribute, which is set to the absolute path of your settings module⁶⁵. The call to os.path.dirname() then provides the reference to the absolute path of the directory containing the settings.py module. Calling os.path.dirname() again removes another layer, so that BASE_DIR contains <workspace>/tango_with_django_project/. You can see this process in action, if you are curious, by adding the following lines to your settings.py file.

 $^{^{62}} http://en.wikipedia.org/wiki/Hard_coding$

⁶³http://sourcemaking.com/antipatterns

⁶⁴http://en.wikipedia.org/wiki/Software_portability

⁶⁵http://stackoverflow.com/a/9271479

```
print(__file__)
print(os.path.dirname(__file__))
print(os.path.dirname(os.path.dirname(__file__)))
```

Having access to the value of BASE_DIR makes it easy for you to reference other aspects of your Django project. As such, we can now create a new variable called TEMPLATE_DIR that will reference your new templates directory. We can make use of the os.path.join() function to join up multiple paths, leading to a variable definition like the example below.

```
TEMPLATE_DIR = os.path.join(BASE_DIR, 'templates')
```

Here we make use of os.path.join() to mash together the BASE_DIR variable and 'templates', which would yield workspace>/tango_with_django_project/templates/. This means we can then use our new TEMPLATE_DIR variable to replace the hard coded path we defined earlier in TEMPLATES. Update the DIRS key/value pairing to look like the following.

```
'DIRS': [TEMPLATE_DIR, ]
```

Why TEMPLATE_DIR?

You've created a new variable called TEMPLATE_DIR at the top of your settings.py file because it's easier to access should you ever need to change it. For more complex Django projects, the DIRS list allows you to specify more than one template directory - but for this book, one location is sufficient to get everything working.

Concatenating Paths

When concatenating system paths together, always use os.path.join(). Using this built-in function ensures that the correct path separators are used. On a UNIX operating system (or derivative of), forward slashes (/) would be used to separate directories, whereas a Windows operating system would use backward slashes (\). If you manually append slashes to paths, you may end up with path errors when attempting to run your code on a different operating system, thus reducing your project's portability.

Adding a Template

With your template directory and path now set up, create a file called index.html and place it in the templates/rango/ directory. Within this new file, add the following HTML code.

```
<!DOCTYPE html>
<html>
    <head>
        <title>Rango</title>
    </head>
    <body>
        <h1>Rango says...</h1>
        <div>
            hey there partner! <br />
            <strong>{{ boldmessage }}</strong><br />
        </div>
        <div>
            <a href="/rango/about/">About</a><br />
        </div>
    </body>
</html>
```

From this HTML code, it should be clear that a simple HTML page is going to be generated that greets a user with a *hello world* message. You might also notice some non-HTML in the form of {{ boldmessage }}. This is a *Django template variable*. We can set values to these variables so they are replaced with whatever we want when the template is rendered. We'll get to that in a moment.

To use this template, we need to reconfigure the index() view that we created earlier. Instead of dispatching a simple response, we will change the view to dispatch our template.

In rango/views.py, check to see if the following import statement exists at the top of the file. If it is not present, add it.

```
from django.shortcuts import render
```

You can then update the index() view function as follows. Check out the inline commentary to see what each line does.

```
def index(request):
    # Construct a dictionary to pass to the template engine as its context.
# Note the key boldmessage is the same as {{ boldmessage }} in the template!
    context_dict = {'boldmessage': "Crunchy, creamy, cookie, candy, cupcake!"}

# Return a rendered response to send to the client.
# We make use of the shortcut function to make our lives easier.
# Note that the first parameter is the template we wish to use.
    return render(request, 'rango/index.html', context=context_dict)
```

First, we construct a dictionary of key/value pairs that we want to use within the template. Then, we call the render() helper function. This function takes as input the user's request, the template filename, and the context dictionary. The render() function will take this data and mash it together with the template to produce a complete HTML page that is returned with a *HttpResponse*. This response is then returned and dispatched to the user's web browser.

What is the Template Context?

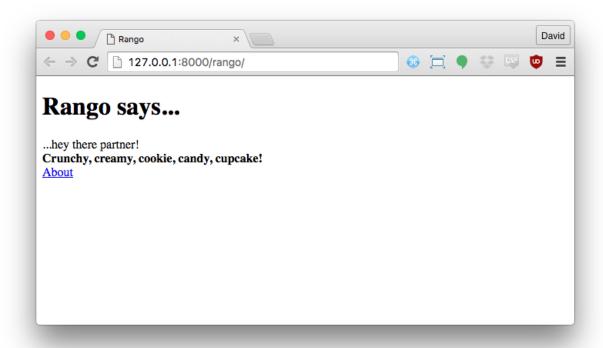

When a template file is loaded with the Django templating system, a *template context* is created. In simple terms, a template context is a Python dictionary that maps template variable names with Python variables. In the template we created above, we included a template variable name called boldmessage. In our updated index(request) view example, the string Crunchy, creamy, cookie, candy, cupcake! is mapped to template variable boldmessage. The string Crunchy, creamy, cookie, candy, cupcake! therefore replaces any instance of {{ boldmessage }} within the template.

Now that you have updated the view to employ the use of your template, start the Django development server and visit http://127.0.0.1:8000/rango/. You should see your simple HTML template rendered, just like the example screenshot shown below.

If you don't, read the error message presented to see what the problem is, and then double check all the changes that you have made. One of the most common issues people have with templates is that the path is set incorrectly in settings.py. Sometimes it's worth adding a print statement to settings.py to report the BASE_DIR and TEMPLATE_DIR to make sure everything is correct.

This example demonstrates how to use templates within your views. However, we have only touched upon a fraction of the functionality provided by the Django templating engine. We will use templates in more sophisticated ways as you progress through this book. In the meantime, you can find out more about templates from the official Django documentation⁶⁶.

⁶⁶https://docs.djangoproject.com/en/2.0/ref/templates/

What you should see when your first template is working correctly. Note the bold text - Crunchy, creamy, cookie, candy, cupcake! - which originates from the view, but is rendered in the template.

Serving Static Media Files

While you've got templates working, your Rango app is admittedly looking a bit plain right now - there's no styling or imagery. We can add references to other files in our HTML template such as *Cascading Style Sheets* (*CSS*)⁶⁷, *JavaScript*⁶⁸ and images to improve the presentation. These are called *static files*, because they are not generated dynamically by a Web server; they are simply sent as is to a client's Web browser. This section shows you how to set Django up to serve static files, and shows you how to include an image within your simple template.

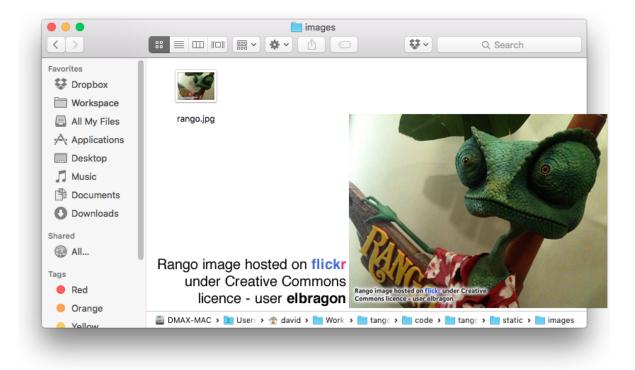

Configuring the Static Media Directory

To start, you will need to set up a directory in which static media files are stored. In your project directory (e.g. <workspace>/tango_with_django_project/), create a new directory called static and a new directory called images inside static. Check that the new static directory is at the same level as the templates directory you created earlier in this chapter.

 $^{^{67}} http://en.wikipedia.org/wiki/Cascading_Style_Sheets$

⁶⁸https://en.wikipedia.org/wiki/JavaScript

Next, place an image inside the images directory. As shown in below, we chose a picture of the chameleon Rango⁶⁹ - a fitting mascot, if ever there was one.

Rango the chameleon within our static/images media directory.

Just like the templates directory we created earlier, we need to tell Django about our new static directory. To do this, we once again need to edit our project's settings.py module. Within this file, we need to add a new variable pointing to our static directory, and a data structure that Django can parse to work out where our new directory is.

First of all, create a variable called STATIC_DIR at the top of settings.py, preferably underneath BASE_DIR and TEMPLATES_DIR to keep your paths all in the same place. STATIC_DIR should make use of the same os.path.join trick - but point to static this time around, just as shown below.

```
STATIC_DIR = os.path.join(BASE_DIR, 'static')
```

This will provide an absolute path to the location workspace>/tango_with_django_project/static/. Once this variable has been created, we then need to create a new data structure called STATICFILES_-DIRS. This is essentially a list of paths with which Django can expect to find static files that can be served. By default, this list does not exist - check it doesn't before you create it. If you define it twice, you can start to confuse Django - and yourself.

For this book, we're only going to be using one location to store our project's static files - the path defined in STATIC_DIR. As such, we can simply set up STATICFILES_DIRS with the following.

⁶⁹http://www.imdb.com/title/tt1192628/

STATICFILES_DIRS = [STATIC_DIR,]

Keep settings.py Tidy!

It's in your best interests to keep your settings.py module tidy and in good order. Don't just put things in random places; keep it organised. Keep your DIRS variables at the top of the module so they are easy to find, and place STATICFILES_DIRS in the portion of the module responsible for static media (close to the bottom). When you come back to edit the file later, it'll be easier for you or other collaborators to find the necessary variables.

Finally, check that the STATIC_URL variable is defined within your settings.py module. If it is not, then define it as shown below. Note that this variable by default in Django appears close to the end of the module, so you may have to scroll down to find it.

```
STATIC_URL = '/static/'
```

With everything required now entered, what does it all mean? Put simply, the first two variables STATIC_DIR and STATICFILES_DIRS refers to the locations on your computer where static files are stored. The final variable STATIC_URL then allows us to specify the URL with which static files can be accessed when we run our Django development server. For example, with STATIC_URL set to /static/, we would be able to access static content at http://127.0.0.1:8000/static/. Think of the first two variables as server-side locations, and the third variable as the location with which clients can access static content.

Test your Configuration

As a small exercise, test to see if everything is working correctly. Try and view the rango.jpg image in your browser when the Django development server is running. If your STATIC_URL is set to /static/ and rango.jpg can be found at images/rango.jpg, what is the URL you enter into your Web browser's window?

Try to figure this out before you move on! The answer is coming up if you get stuck.

Don't Forget the Slashes!

When setting STATIC_URL, check that you end the URL you specify with a forward slash (e.g. /static/, not /static). As per the official Django documentation⁷⁰, not doing so can open you up to a world of pain. The extra slash at the end ensures that the root of the URL (e.g. /static/) is separated from the static content you want to serve (e.g. images/rango.jpg).

⁷⁰https://docs.djangoproject.com/en/1.9/ref/settings/#std:setting-STATIC URL

Serving Static Content

While using the Django development server to serve your static media files is fine for a development environment, it's highly unsuitable for a production environment. The official Django documentation on deployment⁷¹ provides further information about deploying static files in a production environment. We'll look at this issue in more detail however when we deploy Rango.

If you haven't managed to figure out where the image should be accessible from, point your web browser to http://127.0.0.1:8000/static/images/rango.jpg.

Static Media Files and Templates

Now that you have your Django project set up to handle static files, you can now make use of these files within your templates to improve their appearance and add additional functionality.

To demonstrate how to include static files, open up the index.html templates you created earlier, located in the <workspace>/templates/rango/ directory. Modify the HTML source code as follows. The two lines that we add are shown with a HTML comment next to them for easy identification.

```
<!DOCTYPE html>
{% load staticfiles %} <!-- New line -->
<html>
    <head>
        <title>Rango</title>
    </head>
    <body>
        <h1>Rango says...</h1>
        <div>
            hey there partner! <br />
            <strong>{{ boldmessage }}</strong><br />
        </div>
        <div>
            <a href="/rango/about/">About</a><br />
            <img src="{% static "images/rango.jpg" %}"</pre>
                 alt="Picture of Rango" /> <!-- New line -->
        </div>
```

⁷¹https://docs.djangoproject.com/en/2.0/howto/static-files/deployment/

```
</body>
```

The first new line added ({% load staticfiles %}) informs Django's template engine that we will be using static files within the template. This then enables us to access the media in the static directories via the use of the static template tag⁷². This indicates to Django that we wish to show the image located in the static media directory called images/rango.jpg. Template tags are denoted by curly brackets (e.g. {% %}), and calling static will combine the URL specified in STATIC_URL with images/rango.jpg to yield /static/images/rango.jpg. The HTML generated by the Django template engine would be:

```
<img src="/static/images/rango.jpg" alt="Picture of Rango" />
```

If for some reason the image cannot be loaded, it is always a good idea to specify an alternative text tagline. This is what the alt attribute provides inside the img tag. You can see what happens in the image below.

Rango says...

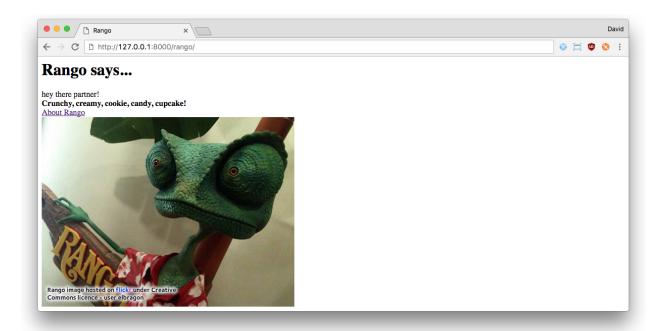

hey there partner! I am bold font from the context
About Rango

Picture of
Rango

The image of Rango couldn't be found, and is instead replaced with a placeholder containing the text from the img alt attribute.

With these minor changes in place, start the Django development server once more and navigate to http://127.0.0.1:8000/rango. If everything has been done correctly, you will see a Webpage that looks similar to the screenshot shown below.

⁷²https://docs.djangoproject.com/en/2.0/ref/templates/builtins/

Our first Rango template, complete with a picture of Rango the chameleon.

Templates and <!DOCTYPE>

When creating the HTML templates, always ensure that the DOCTYPE declaration⁷³ appears on the **first line**. If you put the {% load staticfiles %} template command first, then whitespace will be added to the rendered template before the DOCTYPE declaration. This whitespace will lead to your HTML markup failing validation⁷⁴.

⁷³http://www.w3schools.com/tags/tag_doctype.asp

⁷⁴https://validator.w3.org/

Loading other Static Files

The {% static %} template tag can be used whenever you wish to reference static files within a template. The code example below demonstrates how you could include JavaScript, CSS and images into your templates with correct HTML markup.

```
<!DOCTYPE html>
{% load staticfiles %}
<html>
    <head>
        <title>Rango</title>
        <!-- CSS -->
        <link rel="stylesheet" href="{% static "css/base.css" %}" />
        <!-- JavaScript -->
        <script src="{% static "js/jquery.js" %}"></script>
    </head>
    <body>
        <!-- Image -->
        <img src="{% static "images/rango.jpg" %}" alt="A chameleon lizard called Ra\</pre>
ngo" />
    </body>
</html>
```

Static files you reference will obviously need to be present within your static directory. If a requested file is not present or you have referenced it incorrectly, the console output provided by Django's development server will show a HTTP 404 error⁷⁵. Try referencing a non-existent file and see what happens. Looking at the output snippet below, notice how the last entry's HTTP status code is 404.

```
[10/Apr/2016 15:12:48] "GET /rango/ HTTP/1.1" 200 374
[10/Apr/2016 15:12:48] "GET /static/images/rango.jpg HTTP/1.1" 304 0
[10/Apr/2016 15:12:52] "GET /static/images/not-here.jpg HTTP/1.1" 404 0
```

For further information about including static media you can read through the official Django documentation on working with static files in templates⁷⁶.

⁷⁵https://en.wikipedia.org/wiki/HTTP_404

⁷⁶https://docs.djangoproject.com/en/2.0/howto/static-files/#staticfiles-in-templates

Serving Media

Static media files can be considered files that don't change and are essential to your application. However, often you will have to store *media files* which are dynamic in nature. These files can be uploaded by your users or administrators, and so they may change. As an example, a media file would be a user's profile picture. If you run an e-commerce website, a series of media files would be used as images for the different products that your online shop has.

In order to serve media files successfully, we need to update Django project's settings. This section details what you need to add - but we won't be fully testing it out until later where we implement the functionality for users to upload profile pictures.

Serving Media Files

Like serving static content, Django provides the ability to serve media files in your development environment - to make sure everything is working. The methods that Django uses to serve this content are highly unsuitable for a production environment, so you should be looking to host your app's media files by some other means. The deployment chapter will discuss this in more detail.

Modifying settings.py

First open your Django project's settings.py module. In here, we'll be adding a couple more things. Like static files, media files are uploaded to a specified directory on your filesystem. We need to tell Django where to store these files.

At the top of your settings.py module, locate your existing BASE_DIR, TEMPLATE_DIR and STATIC_-DIR variables - they should be close to the top. Underneath, add a further variable, MEDIA_DIR.

```
MEDIA_DIR = os.path.join(BASE_DIR, 'media')
```

This line instructs Django that media files will be uploaded to your Django project's root, plus '/media' - or <workspace>/tango_with_django_project/media/. As we previously mentioned, keeping these path variables at the top of your settings.py module makes it easy to change paths later on if necessary.

Now find a blank spot in settings.py, and add two more variables. The variables MEDIA_ROOT and MEDIA_URL will be picked up and used by Django to set up media file hosting⁷⁷.

 $^{^{77}} https://docs.djangoproject.com/en/2.0/howto/static-files/\#serving-files-uploaded-by-a-user-during-development$

```
MEDIA_ROOT = MEDIA_DIR
MEDIA_URL = '/media/'
```

Once again, don't Forget the Slashes!

Like the STATIC_URL variable, ensure that MEDIA_URL ends with a forward slash (i.e. /media/, not /media). The extra slash at the end ensures that the root of the URL (e.g. /media/) is separated from the content uploaded by your app's users.

The two variables tell Django where to look in your filesystem for media files (MEDIA_ROOT) that have been uploaded/stored, and what URL to serve them from (MEDIA_URL). With the configuration defined above, the uploaded file cat.jpg will for example be available on your Django development server at http://localhost:8000/media/cat.jpg.

When we come to working with templates later on in this book, it'll be handy for us to obtain a reference to the MEDIA_URL path when we need to reference uploaded content. Django provides a *template context processor*⁷⁸ that'll make it easy for us to do. While we don't strictly need this set up now, it's a good time to add it in.

To do this, find the TEMPLATES list in settings.py. Within that list, look for the nested context_processors list, and within that list, add a new processor, django.template.context_processors.media. Your context_processors list should then look similar to the example below.

```
'context_processors': [
    'django.template.context_processors.debug',
    'django.template.context_processors.request',
    'django.contrib.auth.context_processors.auth',
    'django.contrib.messages.context_processors.messages',
    'django.template.context_processors.media'
],
```

Tweaking your URLs

The final step for setting up the serving of media in a development environment is to tell Django to serve static content from MEDIA_URL. This can be achieved by opening your project's urls.py module, and modifying it by appending a call to the static() function to your project's urlpatterns list.

⁷⁸ https://docs.djangoproject.com/en/2.0/ref/templates/api/#django-template-context-processors-media

You'll also need to add the following import statements at the top of the urls.py module.

```
from django.conf import settings
from django.conf.urls.static import static
```

Once this is complete, you should be able to serve content from the media directory of your project from the /media/ URL.

Basic Workflow

With the chapter complete, you should now know how to setup and create templates, use templates within your views, setup and use the Django development server to serve static media files, *and* include images within your templates. We've covered quite a lot!

Creating a template and integrating it within a Django view is a key concept for you to understand. It takes several steps, but will become second nature to you after a few attempts.

- 1. First, create the template you wish to use and save it within the templates directory you specified in your project's settings.py module. You may wish to use Django template variables (e.g. {{ variable_name }}) or template tags⁷⁹ within your template. You'll be able to replace these with whatever you like within the corresponding view.
- 2. Find or create a new view within an application's views.py file.
- 3. Add your view specific logic (if you have any) to the view. For example, this may involve extracting data from a database and storing it within a list.
- 4. Within the view, construct a dictionary object which you can pass to the template engine as part of the template's *context*.
- 5. Make use of the render() helper function to generate the rendered response. Ensure you reference the request, then the template file, followed by the context dictionary.
- 6. If you haven't already done so, map the view to a URL by modifying your project's urls.py file and the application specific urls.py file if you have one.

The steps involved for getting a static media file onto one of your pages are part of another important process that you should be familiar with. Check out the steps below on how to do this.

1. Take the static media file you wish to use and place it within your project's static directory. This is the directory you specify in your project's STATICFILES_DIRS list within settings.py.

⁷⁹https://docs.djangoproject.com/en/2.0/ref/templates/builtins/

2. Add a reference to the static media file to a template. For example, an image would be inserted into an HTML page through the use of the tag.

3. Remember to use the {% load staticfiles %} and {% static "<filename>" %} commands within the template to access the static files. Replace <filename> with the path to the image or resource you wish to reference. Whenever you wish to refer to a static file, use the static template tag!

The steps for serving media files are similar to those for serving static media.

- 1. Place a file within your project's media directory. The media directory is specified by your project's MEDIA_ROOT variable.
- 2. Link to the media file in a template through the use of the {{ MEDIA_URL }} context variable.
 For example, referencing an uploaded image cat.jpg would have an tag like .

Exercises

Give the following exercises a go to reinforce what you've learnt from this chapter.

- Convert the about page to use a template as well, using a template called about.html.
- Within the new about.html template, add a picture stored within your project's static files.
- On the about page, include a line that says, This tutorial has been put together by <your-name>.
- In your Django project directory, create a new directory called media, download a picture of a cat and save it to the media directory as cat.jpg.
- In your **about page**, add in the tag to display the picture of the cat, to ensure that your media is being served correctly. Keep the static image of Rango in your index page so that your app has working examples of both static and media files.

Static and Media Files

Remember: static files, as the name implies, do not change. These files form the core components of your website. Media files are user defined; and as such, they may change often!

An example of a static file could be a stylesheet file (css), which determines the appearance of your app's webpages. An example of a media file could be a user profile image, which is uploaded by the user when they create an account on your app.

Tests

We have written a few tests to check if you have completed the exercises. To check your work so far, download the tests.py script⁸⁰ from our GitHub repository⁸¹, and save it within your rango app directory.

It is good practice to write tests as you go to make sure the application is working as expected. To run the tests, issue the following command in the terminal or Command Prompt.

\$ python manage.py test rango

If you are interested in learning about automated testing, now is a good time to check out the chapter on testing. The chapter runs through some of the basics on how you can write tests to automatically check the integrity of your code.

However for the time being you can see if you pass the tests. If you don't check carefully the test out put and see what tests you fail on - then go back to your code and update it to meet the test requirements.

^{*}Ohttps://github.com/leifos/tango_with_django_2/blob/master/code/tango_with_django_project/rango/tests.py
*Ihttps://github.com/leifos/tango_with_django_2/

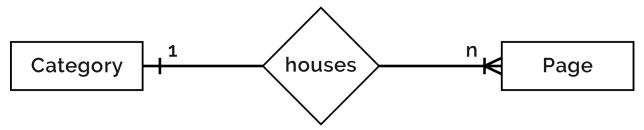

Typically web applications require a back end to store the dynamic content that appears on the website. For Rango, we need to store the pages and the categories, along with other details. The most convention way is to do so by employing the services of a relational database - that uses *Structured Query Language (SQL)*. Django, however, provides a convienent way in which to access data stored in databases by using an *Object Relational Mapper (ORM)*⁸². In essence, data stored within a database table is encapsulated via Django *models*. A model is a Python object that describes the database table's data. Instead of directly working on the database via SQL, Django provides methods that let you manipulate the data via the corresponding Python model object.

This chapter walks you through the basics of data management with Django and its ORM. You'll find it's incredibly easy to add, modify and delete data within your app's underlying database, and how straightforward it is to get data from the database to the Web browsers of your users.

Rango's Requirements

Before we get started, let's go over the data requirements for the Rango app that we are developing. Full requirements for the application are provided in detail earlier on, but to refresh your memory, let's quickly summarise our client's requirements.

- Rango is essentially a *web page directory* a site containing links to other websites.
- There are a number of different *webpage categories* with each category housing a number of links. We assumed in the overview chapter that this is a one-to-many relationship. Check out the Entity Relationship diagram below.
- A category has a name, a number of visits, and a number of likes.
- A page refers to a category, has a title, URL and a number of views.

The Entity Relationship Diagram of Rango's two main entities.

⁸²https://en.wikipedia.org/wiki/Object-relational_mapping

Telling Django about Your Database

Before we can create any models, we need to set up our database with Django. In Django, a DATABASES variable is automatically created in your settings.py module when you set up a new project. It'll look similar to the following example.

```
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.sqlite3',
        'NAME': os.path.join(BASE_DIR, 'db.sqlite3'),
    }
}
```

We can pretty much leave this as is for our Rango app. You can see a default database that is powered by a lightweight database engine, SQLite⁸³ (see the ENGINE option). The NAME entry for this database is the path to the database file, which is by default db.sqlite3 in the root of your Django project.

Git Top Tip

If you are using Git, you might be tempted to add and commit the database file. This is not a good idea because if you are working on your app with other people, they are likely to change the database and this will cause endless conflicts.

Instead, add db.sqlite3 to your .gitignore file so that it won't be added when you git commit and git push. You can also do this for other files like *.pyc and machine specific files.

Using other Database Engines

The Django database framework has been created to cater for a variety of different database backends, such as PostgresSQL⁸⁴, MySQL⁸⁵ and Microsoft's SQL Server⁸⁶. For other database engines, other keys like USER, PASSWORD, HOST and PORT exist for you to configure the database with Django.

While we don't cover how to use other database engines in this book, there are guides online which show you how to do this. A good starting point is the official Django documentation⁸⁷.

Note that SQLite is sufficient for demonstrating the functionality of the Django ORM. When you find your app has become viral and has accumulated thousands of users, you may want to consider switching the database backend to something more robust⁸⁸.

⁸³https://www.sqlite.org/

⁸⁴http://www.postgresql.org/

⁸⁵https://www.mysql.com/

⁸⁶https://en.wikipedia.org/wiki/Microsoft_SQL_Server

⁸⁷https://docs.djangoproject.com/en/2.0/ref/databases/#storage-engines

⁸⁸http://www.sqlite.org/whentouse.html

Creating Models

With your database configured in settings.py, let's create the two initial data models for the Rango application. Models for a Django app are stored in the respective models.py module. This means that for Rango, models are stored within rango/models.py.

For the models themselves, we will create two classes - one class representing each model. Both must inherit⁸⁹ from the Model base class, django.db.models.Model. The two Python classes will be the definitions for models representing *categories* and *pages*. Define the Category and Page model as follows.

```
class Category(models.Model):
    name = models.CharField(max_length=128, unique=True)

def __str__(self):
    return self.name

class Page(models.Model):
    category = models.ForeignKey(Category, on_delete=models.CASCADE)
    title = models.CharField(max_length=128)
    url = models.URLField()
    views = models.IntegerField(default=0)

def __str__(self):
    return self.title
```

Check import Statements

At the top of the models.py module, you should see from django.db import models. If you don't see it, add it in.

```
__str__() Or __unicode__()?
```

The __str__() and __unicode__() methods in Python generate a string representation of the class (similar to the toString() method in Java). In Python 2.x, strings are represented in ASCII format in the __str__() method. If you want Unicode support⁹⁰, then you need to also implement the __unicode__() method.

In Python 3.x, strings are Unicode by default - so you only need to implement the __str__() method.

⁸⁹https://en.wikipedia.org/wiki/Inheritance (object-oriented programming)

⁹⁰https://docs.python.org/2/howto/unicode.html

When you define a model, you need to specify the list of fields and their associated types, along with any required or optional parameters. By default, all models have an auto-increment integer field called id which is automatically assigned and acts a primary key.

Django provides a comprehensive series of built-in field types⁹¹. Some of the most commonly used are detailed below.

- CharField, a field for storing character data (e.g. strings). Specify max_length to provide a maximum number o characters the field can store.
- URLField, much like a CharField, but designed for storing resource URLs. You may also specify a max_length parameter.
- IntegerField, which stores integers.
- DateField, which stores a Python datetime.date object.

Other Field Types

Check out the Django documentation on model fields⁹² for a full listing of the Django field types you can use, along with details on the required and optional parameters that each has.

For each field, you can specify the unique attribute. If set to True, the given field's value must be unique throughout the underlying database table that is mapped to the associated model. For example, take a look at our Category model defined above. The field name has been set to unique, meaning that every category name must be unique. This means that you can use the field like a primary key.

You can also specify additional attributes for each field, such as stating a default value with the syntax default='value', and whether the value for a field can be blank (or NULL⁹³) (null=True) or not (null=False).

Django provides three types of fields for forging relationships between models in your database. These are:

- ForeignKey, a field type that allows us to create a one-to-many relationship 94;
- OneToOneField, a field type that allows us to define a strict one-to-one relationship 5; and
- ManyToManyField, a field type which allows us to define a many-to-many relationship⁹⁶.

From our model examples above, the field category in model Page is of type ForeignKey. This allows us to create a one-to-many relationship with model/table Category, which is specified as

⁹¹https://docs.djangoproject.com/es/2.0/ref/models/fields/#model-field-types

⁹²https://docs.djangoproject.com/es/2.0/ref/models/fields/#model-field-types

⁹³https://en.wikipedia.org/wiki/Nullable_type

⁹⁴https://en.wikipedia.org/wiki/One-to-many_(data_model)

⁹⁵https://en.wikipedia.org/wiki/One-to-one_(data_model)

⁹⁶https://en.wikipedia.org/wiki/Many-to-many_(data_model)

an argument to the field's constructor. When specifying the foreign key, we also need to include instructions to Django on how to handle the situation when the category that the page belongs to is deleted. ONCASCADE instructs Django to delete the pages associated with the category, if the category is deleted. However, there are other settings which will provide Django with other instructions on how to handle this situation. See the Django documentation on Foreign Keys⁹⁷ for more details.

Finally, it is good practice to implement the __str__() method. Without this method implemented when you go to print the object, it will show as <Category: Category object>. This isn't very useful when debugging or accessing the object - instead the code above will print, for example, <Category: Python> for the Python category. It is also helpful when we go to use the Admin Interface because Django will display the string representation of the object.

Creating and Migrating the Database

With our models defined in models.py, we can now let Django work its magic and create the tables in the underlying database. Django provides what is called a *migration tool*⁹⁸ to help us set up and update the database to reflect any changes to your models. For example, if you were to add a new field then you can use the migration tools to update the database.

Setting up

First of all, the database must be *initialised*. This means creating the database and all the associated tables so that data can then be stored within it. To do this, you must open a terminal or command prompt, and navigate to your project's root directory - where manage.py is stored. Run the following command, *bearing in mind that the output may vary from what you see below*.

\$ python manage.py migrate

Operations to perform:

Apply all migrations: admin, auth, contenttypes, sessions

⁹⁷ https://docs.djangoproject.com/en/2.0/ref/models/fields/#django.db.models.ForeignKey

⁹⁸https://en.wikipedia.org/wiki/Data_migration

```
1
    Running migrations:
            Applying contenttypes.0001_initial... OK
 3
            Applying auth.0001_initial... OK
            Applying admin.0001_initial... OK
            Applying admin.0002_logentry_remove_auto_add... OK
 5
            Applying contenttypes.0002_remove_content_type_name... OK
 6
 7
            Applying auth.0002_alter_permission_name_max_length... OK
            Applying auth.0003_alter_user_email_max_length... OK
8
            Applying auth.0004_alter_user_username_opts... OK
9
            Applying auth.0005_alter_user_last_login_null... OK
10
            Applying auth.0006_require_contenttypes_0002... OK
11
            Applying auth.0007_alter_validators_add_error_messages... OK
12
13
            Applying auth.0008_alter_user_username_max_length... OK
14
            Applying auth.0009_alter_user_last_name_max_length... OK
            Applying sessions.0001_initial... OK
15
```

All apps that are installed in your Django project (check INSTALLED_APPS in settings.py) will update their database representations with this command. After this command is issued, you should then see a db.sqlite3 file in your Django project's root.

Next, create a superuser to manage the database. Run the following command.

```
$ python manage.py createsuperuser
```

The superuser account will be used to access the Django admin interface, used later on in this chapter. Enter a username for the account, e-mail address and provide a password when prompted. Once completed, the script should finish successfully. Make sure you take a note of the username and password for your superuser account.

Creating and Updating Models/Tables

Whenever you make changes to your app's models, you need to *register* the changes via the makemigrations command in manage.py. Specifying the rango app as our target, we then issue the following command from our Django project's root directory.

```
$ python manage.py makemigrations rango
Migrations for 'rango':
    rango/migrations/0001_initial.py
    - Create model Category
    - Create model Page
```

Upon the completion of this command, check the rango/migrations directory to see that a Python script has been created. It's called <code>0001_initial.py</code>, which contains all the necessary details to create your database schema for that particular migration.

Checking the Underlying SQL

If you want to check out the underlying SQL that the Django ORM issues to the database engine for a given migration, you can issue the following command.

```
$ python manage.py sqlmigrate rango 0001
```

In this example, rango is the name of your app, and 0001 is the migration you wish to view the SQL code for. Doing this allows you to get a better understanding of what exactly is going on at the database layer, such as what tables are created. You may find for complex database schemas including a many-to-many relationship that additional tables are created for you.

After you have created migrations for your app, you need to commit them to the database. Do so by once again issuing the migrate command.

This output confirms that the database tables have been created in your database, and you are good to go.

However, you may have noticed that our Category model is currently lacking some fields that were specified in Rango's requirements. Don't worry about this, as these will be added in later, allowing you to go through the migration process again.

Django Models and the Shell

Before we turn our attention to demonstrating the Django admin interface, it's worth noting that you can interact with Django models directly from the Django shell - a very useful tool for debugging purposes. We'll demonstrate how to create a Category instance using this method.

To access the shell, we need to call manage.py from within your Django project's root directory once more. Run the following command.

```
$ python manage.py shell
```

This will start an instance of the Python interpreter and load in your project's settings for you. You can then interact with the models, with the following terminal session demonstrating this functionality. Check out the inline commentary that we added to see what each command achieves. Note there are slight differences between what Django 1.9 and Django 1.10 return – these are both demonstrated below, complete with commentary.

```
# Import the Category model from the Rango application
>>> from rango.models import Category

# Show all the current categories
>>> print(Category.objects.all())
# Since no categories have been defined we get an empty QuerySet object.

<QuerySet []>

# Create a new category object, and save it to the database.
>>> c = Category(name="Test")
>>> c.save()

# Now list all the category objects stored once more.
>>> print(Category.objects.all())
# You'll now see a 'Test' category.

<QuerySet [<Category: Test>]

# Quit the Django shell.
>>> quit()
```

In the example, we first import the model that we want to manipulate. We then print out all the existing categories. As our underlying Category table is empty, an empty list is returned. Then we create and save a Category, before printing out all the categories again. This second print then shows the new Category just added. Note the name, Test appears in the second print - this is the str () method at work!

Complete the Official Tutorial

The example above is only a very basic taster on database related activities you can perform in the Django shell. If you have not done so already, it's now a good time to complete part two of the official Django Tutorial to learn more about interacting with models⁹⁹. Also check out the official Django documentation on the list of available commands¹⁰⁰ for working with models.

⁹⁹https://docs.djangoproject.com/en/2.0/intro/tutorial02/

¹⁰⁰ https://docs.djangoproject.com/en/2.0/ref/django-admin/#available-commands

Configuring the Admin Interface

One of the standout features of Django is the built-in, Web-based administrative (or *admin*) interface that allows you to browse, edit and delete data represented as model instances (from the corresponding database tables). In this section, we'll be setting the admin interface up so you can see the two Rango models you have created so far.

Setting everything up is relatively straightforward. In your project's settings.py module, you will notice that one of the preinstalled apps (within the INSTALLED_APPS list) is django.contrib.admin. Furthermore, there is a urlpattern that matches admin/ within your project's urls.py module.

By default, things are pretty much ready to go. Start the Django development server in the usual way with the following command.

```
$ python manage.py runserver
```

Navigate your Web browser to http://127.0.0.1:8000/admin/. You are then presented with a login prompt. Login using the credentials you created previously with the \$ python manage.py createsuperuser command. You are then presented with an interface looking similar to the one shown below.

The Django admin interface, sans Rango models.

While this looks good, we are missing the Category and Page models that were defined for the Rango app. To include these models, we need to give Django some help.

To do this, open the file rango/admin.py. With an include statement already present, modify the module so that you register each class you want to include. The example below registers both the Category and Page class to the admin interface.

```
from django.contrib import admin
from rango.models import Category, Page
admin.site.register(Category)
admin.site.register(Page)
```

Adding further classes which may be created in the future is as simple as adding another call to the admin.site.register() method.

With these changes saved, either reload the admin web pages, or restart the Django development server and revisit the admin interface at http://127.0.0.1:8000/admin/. You will now see the Category and Page models, as shown below.

The Django admin interface, complete with Rango models.

Try clicking the Categorys link within the Rango section. From here, you should see the Test category that we created earlier via the Django shell.

Experiment with the Admin Interface

You'll be using the admin interface quite a bit to verify data is stored correctly as you develop the Rango app. Experiment with it, and see how it all works. The interface is self-explanatory and straightforward to understand.

Delete the Test category that was previously created. We'll be populating the database shortly with example data.

User Management

The Django admin interface is your port of call for user management, through the Authentication and Authorisation section. Here, you can create, modify and delete user accounts, and varying privilege levels.

Plural vs. Singular Spellings

Note the typo within the admin interface (Categorys, not Categories). This typo can be fixed by adding a nested Meta class into your model definitions with the verbose_name_plural attribute. Check out a modified version of the Category model below for an example, and Django's official documentation on models¹⁰¹ for more information about what can be stored within the Meta class.

```
class Category(models.Model):
    name = models.CharField(max_length=128, unique=True)

class Meta:
    verbose_name_plural = 'Categories'

def __str__(self):
    return self.name
```

¹⁰¹https://docs.djangoproject.com/en/2.0/topics/db/models/#meta-options

Expanding admin.py

It should be noted that the example admin.py module for your Rango app is the most simple, functional example available. However you can customise the Admin interface in a number of ways. Check out the official Django documentation on the admin interface¹⁰² for more information if you're interested.

Creating a Population Script

Entering test data into your database tends to be a hassle. Many developers will add in some bogus test data by randomly hitting keys, like wTFzmN00bz7. Rather than do this, it is better to write a script to automatically populate the database with realistic and credible data. This is because when you go to demo or test your app, you'll see some good examples in the database. Also, if you are deploying the app or sharing it with collaborators, then you/they won't have to go through the process of putting in sample data. It's therefore good practice to create what we call a *population script*.

To create a population script for Rango, start by creating a new Python module within your Django project's root directory (e.g. <workspace>/tango_with_django_project/). Create the populate_rango.py file and add the following code.

```
import os
    os.environ.setdefault('DJANGO_SETTINGS_MODULE',
 2
 3
                           'tango_with_django_project.settings')
 4
    import django
 5
    django.setup()
 6
    from rango.models import Category, Page
8
    def populate():
9
10
        # First, we will create lists of dictionaries containing the pages
        # we want to add into each category.
11
        # Then we will create a dictionary of dictionaries for our categories.
12
        # This might seem a little bit confusing, but it allows us to iterate
13
        # through each data structure, and add the data to our models.
14
15
        python_pages = [
16
            {"title": "Official Python Tutorial",
17
             "url": "http://docs.python.org/2/tutorial/"},
18
            {"title": "How to Think like a Computer Scientist",

                "Other Frameworks": {"pages": other_pages} }
41
        # If you want to add more catergories or pages,
42
        # add them to the dictionaries above.
43
44
        # The code below goes through the cats dictionary, then adds each category,
45
        # and then adds all the associated pages for that category.
46
47
        # if you are using Python 2.x then use cats.iteritems() see
48
        # http://docs.quantifiedcode.com/python-anti-patterns/readability/
        # for more information about how to iterate over a dictionary properly.
49
50
        for cat, cat_data in cats.items():
51
            c = add_cat(cat)
52
            for p in cat_data["pages"]:
53
                add_page(c, p["title"], p["url"])
54
55
        # Print out the categories we have added.
56
        for c in Category.objects.all():
57
            for p in Page.objects.filter(category=c):
58
                print("- {0} - {1}".format(str(c), str(p)))
59
60
61
    def add_page(cat, title, url, views=0):
62
        p = Page.objects.get_or_create(category=cat, title=title)[0]
        p.url=url
63
        p.views=views
64
```

```
65
        p.save()
66
        return p
67
    def add_cat(name):
68
        c = Category.objects.get_or_create(name=name)[0]
69
        c.save()
70
        return c
71
72
    # Start execution here!
73
    if __name__ == '__main__':
74
75
        print("Starting Rango population script...")
        populate()
76
```

Understand this Code!

To reiterate, don't simply copy, paste and leave. Add the code to your new module, and then step through line by line to work out what is going on. It'll help with your understanding.

We've provided explanations below to help you learn from our code!

You should also note that when you see line numbers along side the code, it indicates that we have listed the entire file, rather than code fragments. It also makes things more difficult for you to copy and paste!

While this looks like a lot of code, what is going on is essentially a series of function calls to two small functions, add_page() and add_cat() defined towards the end of the module. Reading through the code, we find that execution starts at the *bottom* of the module - look at lines 75 and 76. This is because above this point, we define functions; these are not executed unless we call them. When the interpreter hits if __name__ == '_main__'^103, we call the populate() function.

What does __name__ == '__main__' Represent?

The __name__ == '__main__' trick is a useful one that allows a Python module to act as either a reusable module or a standalone Python script. Consider a reusable module as one that can be imported into other modules (e.g. through an import statement), while a standalone Python script would be executed from a terminal/Command Prompt by entering python module.py.

Code within a conditional if __name__ == '__main__' statement will therefore only be executed when the module is run as a standalone Python script. Importing the module will not run this code; any classes or functions will however be fully accessible to you.

¹⁰³http://stackoverflow.com/a/419185

Importing Models

When importing Django models, make sure you have imported your project's settings by importing django and setting the environment variable DJANGO_SETTINGS_MODULE to be your project's setting file, as demonstrated in lines 1 to 6 above. You then call django.setup() to import your Django project's settings.

If you don't perform this crucial step, you'll get an exception when attempting to import your models. This is because the necessary Django infrastructure has not yet been initialised. This is why we import Category and Page *after* the settings have been loaded on line 8.

The for loop occupying lines 51-54 is responsible for the calling the add_cat() and add_page() functions repeatedly. These functions are in turn responsible for the creation of new categories and pages. populate() keeps tabs on categories that are created. As an example, a reference to a new category is stored in local variable c - check line 52 above. This is stored because a Page requires a Category reference. After add_cat() and add_page() are called in populate(), the function concludes by looping through all new Category and associated Page objects, displaying their names on the terminal.

Creating Model Instances

We make use of the convenience <code>get_or_create()</code> method for creating model instances in the population script above. As we don't want to create duplicates of the same entry, we can use <code>get_or_create()</code> to check if the entry exists in the database for us. If it doesn't exist, the method creates it. If it does, then a reference to the specific model instance is returned.

This helper method can remove a lot of repetitive code for us. Rather than doing this laborious check ourselves, we can make use of code that does exactly this for us.

The <code>get_or_create()</code> method returns a tuple of (object, created). The first element object is a reference to the model instance that the <code>get_or_create()</code> method creates if the database entry was not found. The entry is created using the parameters you pass to the method - just like <code>category</code>, <code>title</code>, <code>url</code> and <code>views</code> in the example above. If the entry already exists in the database, the method simply returns the model instance corresponding to the entry. <code>created</code> is a boolean value; <code>True</code> is returned if <code>get_or_create()</code> had to create a model instance.

This explanation therefore means that the [0] at the end of our call to the get_or_create() returns the object reference only. Like most other programming language data structures, Python tuples use zero-based numbering¹⁰⁴.

You can check out the official Django documentation¹⁰⁵ for more information on the handy get_or_create() method.

When saved, you can then run your new populations script by changing the present working directory in a terminal to the Django project's root. It's then a simple case of executing the command

¹⁰⁴http://en.wikipedia.org/wiki/Zero-based_numbering

¹⁰⁵https://docs.djangoproject.com/en/2.0/ref/models/querysets/#get-or-create

\$ python populate_rango.py. You should then see output similar to that shown below – the order in which categories are added may vary depending upon how your computer is set up.

```
$ python populate_rango.py
```

Starting Rango population script...

- Python Official Python Tutorial
- Python How to Think like a Computer Scientist
- Python Learn Python in 10 Minutes
- Django Official Django Tutorial
- Django Django Rocks
- Django How to Tango with Django
- Other Frameworks Bottle
- Other Frameworks Flask

Next, verify that the population script actually populated the database. Restart the Django development server, navigate to the admin interface (at http://127.0.0.1:8000/admin/) and check that you have some new categories and pages. Do you see all the pages if you click Pages, like in the figure shown below?

The Django admin interface, showing the Page model populated with the new population script. Success!

While creating a population script may take time, you will save yourself time in the long run. When deploying your app elsewhere, running the population script after setting everything up means you can start demonstrating your app straight away. You'll also find it very handy when it comes to unit testing your code.

Workflow: Model Setup

Now that we've covered the core principles of dealing with Django's ORM, now is a good time to summarise the processes involved in setting everything up. We've split the core tasks into separate sections for you. Check this section out when you need to quickly refresh your mind of the different steps.

Setting up your Database

With a new Django project, you should first tell Django about the database you intend to use (i.e. configure DATABASES in settings.py). You can also register any models in the admin.py module of your app to make them accessible via the admin interface.

Adding a Model

The workflow for adding models can be broken down into five steps.

- 1. First, create your new model(s) in your Django application's models.py file.
- 2. Update admin.py to include and register your new model(s).
- 3. Perform the migration \$ python manage.py makemigrations <app_name>.
- 4. Apply the changes \$ python manage.py migrate. This will create the necessary infrastructure within the database for your new model(s).
- 5. Create/edit your population script for your new model(s).

There will be times when you will have to delete your database – sometimes it's easier to just start afresh. When you want to do this, do the the following. Note that for this tutorial, you are using a SQLite database – Django does support a variety of other database engines¹⁰⁶.

- 1. If you're running it, stop your Django development server.
- 2. For an SQLite database, delete the db.sqlite3 file in your Django project's directory. It'll be in the same directory as the manage.py file.
- 3. If you have changed your app's models, you'll want to run the \$ python manage.py makemigrations <app_name> command, replacing <app_name> with the name of your Django app (i.e. rango). Skip this if your models have not changed.
- 4. Run the \$ python manage.py migrate to create a new database file (if you are running SQLite), and migrate database tables to the database.
- 5. Create a new admin account with the \$ python manage.py createsuperuser command.
- 6. Finally, run your population script again to insert credible test data into your new database.

¹⁰⁶https://docs.djangoproject.com/en/2.0/ref/databases/

Exercises

Now that you've completed this chapter, try out these exercises to reinforce and practice what you have learnt. Once again, note that the following chapters will have expected you to have completed these exercises! If you're stuck, there are some hints to help you complete the exercises below.

- Update the Category model to include the additional attributes views and likes where the default values for each are both zero (0).
- Make the migrations for your app, and then migrate your database to commit the changes.
- Next update your population script so that the Python category has 128 views and 64 likes, the Django category has 64 views and 32 likes, and the Other Frameworks category has 32 views and 16 likes.
- Delete and recreate your database, populating it with your updated population script.
- Complete parts two¹⁰⁷ and seven¹⁰⁸ of the official Django tutorial. These sections will reinforce what you've learnt on handling databases in Django, and show you additional techniques to customising the Django admin interface.
- Customise the admin interface. Change it in such a way so that when you view the Page model, the table displays the category, the name of the page and the url just like in the screenshot shown below. You will need to complete the previous exercises or at least go through the official Django Tutorial to complete this exercise.

The updated admin interface Page view, complete with columns for category and URL.

¹⁰⁷https://docs.djangoproject.com/en/2.0/intro/tutorial02/

¹⁰⁸https://docs.djangoproject.com/en/2.0/intro/tutorial07/

Models and Databases 66

Exercise Hints

If you require some help or inspiration to complete these exercises done, here are some hints.

- Modify the Category model by adding two IntegerFields: views and likes.
- In your population script, you can then modify the add_cat() function to take the values of the views and likes.
 - You'll need to add two parameters to the definition of add_cat() so that views and likes values can be passed to the function, as well as a name for the category.
 - You can then use these parameters to set the views and likes fields within the new Category model instance you create within the add_cat() function. The model instance is assigned to variable c in the population script, as defined earlier in this chapter. As an example, you can access the likes field using the notation c.likes. Don't forget to save() the instance!
 - You then need to update the cats dictionary in the populate() function of your population script. Look at the dictionary. Each key/value pairing¹⁰⁹ represents the *name* of the category as the key, and an additional dictionary containing additional information relating to the category as the *value*. You'll want to modify this dictionary to include views and likes for each category.
 - The final step involves you modifying how you call the add_cat() function. You now have three parameters to pass (name, views and likes); your code currently provides only the name. You need to add the additional two fields to the function call. If you aren't sure how the for loop works over dictionaries, check out this online Python tutorial¹¹⁰. From here, you can figure out how to access the views and likes values from your dictionary.
- After your population script has been updated, you can move on to customising the admin interface. You will need to edit rango/admin.py and create a PageAdmin class that inherits from admin.ModelAdmin.
 - Within your new PageAdmin class, add list_display = ('title', 'category', 'url').
 - Finally, register the PageAdmin class with Django's admin interface. You should modify the line admin.site.register(Page). Change it to admin.site.register(Page, PageAdmin) in Rango's admin.py file.
 - * If you get really stuck look at our code on github¹¹¹!

Models and Databases 67

Tests

Like in the last chapter we have written tests to check if you have completed the chapter and the exercises. To check your work so far, download the tests.py script¹¹² from our GitHub repository¹¹³, and save it within your rango app directory.

Un-comment the Chapter 5 related tests. To run the tests, issue the following command in the terminal or Command Prompt.

\$ python manage.py test rango

If you are interested in learning about automated testing, now is a good time to check out the chapter on testing. The chapter runs through some of the basics on how you can write tests to automatically check the integrity of your code.

 $^{^{112}} https://github.com/leifos/tango_with_django_2/blob/master/code/tango_with_django_project/rango/tests.py$

¹¹³https://github.com/leifos/tango_with_django_2/

Models, Templates and Views

Now that we have the models set up and populated the database with some sample data, we can now start connecting the models, views and templates to serve up dynamic content. In this chapter, we will go through the process of showing categories on the main page, and then create dedicated category pages which will show the associated list of links.

Workflow: Data Driven Page

To do this there are five main steps that you must undertake to create a data driven webpage in Django.

- 1. In views.py file import the models you wish to use.
- 2. In the view function, query the model to get the data you want to present.
- 3. Then pass the results from your model into the template's context.
- 4. Create/modify the template so that it displays the data from the context.
- 5. If you have not done so already, map a URL to your view.

These steps highlight how we need to work within Django's framework to bind models, views and templates together.

Showing Categories on Rango's Homepage

One of the requirements regarding the main page was to show the top five rango'ed categories. To fulfil this requirement, we will go through each of the above steps.

Importing Required Models

First, we need to complete step one. Open rango/views.py and at the top of the file, after the other imports, import the Category model from Rango's models.py file.

```
# Import the Category model
from rango.models import Category
```

Modifying the Index View

Here we will complete step two and step three, where we need to modify the view index() function. Remember that the index() function is responsible for the main page view. Modify index() as follows:

```
def index(request):
    # Query the database for a list of ALL categories currently stored.
    # Order the categories by no. likes in descending order.
    # Retrieve the top 5 only - or all if less than 5.
    # Place the list in our context_dict dictionary
    # that will be passed to the template engine.

category_list = Category.objects.order_by('-likes')[:5]
    context_dict = {'categories': category_list}

# Render the response and send it back!
    return render(request, 'rango/index.html', context_dict)
```

Here, the expression Category.objects.order_by('-likes')[:5] queries the Category model to retrieve the top five categories. You can see that it uses the order_by() method to sort by the number of likes in descending order. The - in -likes denotes that we would like them in descending order (if we removed the - then the results would be returned in ascending order). Since a list of Category objects will be returned, we used Python's list operators to take the first five objects from the list ([:5]) to return a subset of Category objects.

With the query complete, we passed a reference to the list (stored as variable category_list) to the dictionary, context_dict. This dictionary is then passed as part of the context for the template engine in the render() call.

Warning

For this to work, you will have had to complete the exercises in the previous chapter where you need to add the field likes to the Category model.

Modifying the Index Template

With the view updated, we can complete the fourth step and update the template rango/index.html, located within your project's templates directory. Change the HTML so that it looks like the example shown below.

```
<!DOCTYPE html>
{% load staticfiles %}
<html>
<head>
    <title>Rango</title>
</head>
<body>
    <h1>Rango says...</h1>
    <div>
                hey there partner! <br/>
                <strong>{{ boldmessage }}</strong>
        </div>
    <div>
    {% if categories %}
    <u1>
        {% for category in categories %}
            {li>{{ category.name }}
        {% endfor %}
    {% else %}
        <strong>There are no categories present.
    {% endif %}
    </div>
    <div>
        <a href="/rango/about/">About Rango</a><br />
        <img src="{% static "images/rango.jpg" %}" alt="Picture of Rango" />
    </div>
</body>
</html>
```

Here, we make use of Django's template language to present the data using if and for control statements. Within the <body> of the page, we test to see if categories - the name of the context variable containing our list - actually contains any categories ({% if categories %}).

If so, we proceed to construct an unordered HTML list (within the tags). The for loop ({% for category in categories %}) then iterates through the list of results, and outputs each category's name ({{ category.name }}) within a pair of <1i> tags to indicate a list element.

If no categories exist, a message is displayed instead indicating that no categories are present.

As the example shows in Django's template language, all commands are enclosed within the tags {% and %}, while variables are referenced within {{ and }} brackets.

If you now visit Rango's homepage at http://127.0.0.1:8000/rango/, you should see a list of categories underneath the page title just like in the figure below.

The Rango homepage - now dynamically generated - showing a list of categories.

Creating a Details Page

According to the specifications for Rango, we also need to show a list of pages that are associated with each category. We have a number of challenges here to overcome. A new view must be created, which should be parameterised. We also need to create URL patterns and URL strings that encode category names.

URL Design and Mapping

Let's start by considering the URL problem. One way we could handle this problem is to use the unique ID for each category within the URL. For example, we could create URLs like /rango/category/1/ or /rango/category/2/, where the numbers correspond to the categories with unique IDs 1 and 2 respectively. However, it is not possible to infer what the category is about just from the ID.

Instead, we could use the category name as part of the URL. For example, we can imagine that the URL /rango/category/python/ would lead us to a list of pages related to Python. This is a simple, readable and meaningful URL. If we go with this approach, we'll also have to handle categories that have multiple words, like 'Other Frameworks', etc.

Clean your URLs

Designing clean and readable URLs is an important aspect of web design. See Wikipedia's article on Clean URLs¹¹⁴ for more details.

To handle this problem we are going to make use of the slugify function provided by Django.

Update Category Table with a Slug Field

To make readable URLs, we need to include a slug field in the Category model. First we need to import the function slugify from Django that will replace whitespace with hyphens - for example, "how do i create a slug in django" turns into "how-do-i-create-a-slug-in-django".

¹¹⁴http://en.wikipedia.org/wiki/Clean_URL

Unsafe URLs

While you can use spaces in URLs, it is considered to be unsafe to use them. Check out the Internet Engineering Task Force Memo on URLs¹¹⁵ to read more.

Next we need to override the <code>save()</code> method of the <code>Category</code> model, which we will call the <code>slugify</code> method and update the <code>slug</code> field with it. Note that every time the category name changes, the slug will also change. Update your model, as shown below, and add in the import.

```
from django.template.defaultfilters import slugify
...

class Category(models.Model):
    name = models.CharField(max_length=128, unique=True)
    views = models.IntegerField(default=0)
    likes = models.IntegerField(default=0)
    slug = models.SlugField()

def save(self, *args, **kwargs):
    self.slug = slugify(self.name)
    super(Category, self).save(*args, **kwargs)

class Meta:
    verbose_name_plural = 'categories'

def __str__(self):
    return self.name
```

Now that the model has been updated, the changes must now be propagated to the database. However, since data already exists within the database, we need to consider the implications of the change. Essentially, for all the existing category names, we want to turn them into slugs (which is performed when the record is initially saved). When we update the models via the migration tool, it will add the slug field and provide the option of populating the field with a default value. Of course, we want a specific value for each entry - so we will first need to perform the migration, and then re-run the population script. This is because the population script will explicitly call the save() method on each entry, triggering the 'save()' as implemented above, and thus update the slug accordingly for each entry.

To perform the migration, issue the following commands (as detailed in the Models and Databases Workflow).

¹¹⁵http://www.ietf.org/rfc/rfc1738.txt

```
$ python manage.py makemigrations rango
$ python manage.py migrate
```

Since we did not provide a default value for the slug and we already have existing data in the model, the migrate command will give you two options. Select the option to provide a default, and enter an empty string – denoted by two quote marks (i.e. ''). Run the population script again, which will then update the slug fields.

```
$ python populate_rango.py
```

Now run the development server with the command \$ python manage.py runserver, and inspect the data in the models with the admin interface at http://127.0.0.1:8000/admin/.

If you go to add in a new category via the admin interface you may encounter a problem, or two!

- 1. Let's say we added in the category, Python User Groups. If you do so, and try to save the record Django will not let you save it unless you also fill in the slug field too. While we could type in python-user-groups this is error prone. It would be better to have the slug automatically generated.
- 2. The next problem arises if we have one category called Django and one called django. Since the slugify() makes the slugs lower case it will not be possible to identify which category corresponds to the django slug.

To solve the first problem, we can either update our model so that the slug field allows blank entries, i.e.:

```
slug = models.SlugField(blank=True)
```

or we can customise the admin interface so that it automatically pre-populates the slug field as you type in the category name. To do this, update rango/admin.py with the following code.

```
from django.contrib import admin
from rango.models import Category, Page
...
# Add in this class to customise the Admin Interface
class CategoryAdmin(admin.ModelAdmin):
    prepopulated_fields = {'slug':('name',)}
# Update the registration to include this customised interface
admin.site.register(Category, CategoryAdmin)
...
```

Try out the admin interface and add in a new category.

Now that we have addressed the first problem, we can ensure that the slug field is also unique, by adding the constraint to the slug field.

```
slug = models.SlugField(unique=True)
```

Now that we have added in the slug field we can now use the slugs to uniquely identify each category. We could have added the unique constraint earlier, but if we performed the migration and set everything to be an empty string by default it would have raised an error. This is because the unique constraint would have been violated. We could have deleted the database and then recreated everything - but that is not always desirable.

Migration Woes

It's always best to plan out your database in advance and avoid changing it. Making a population script means that you easily recreate your database if you need to delete it.

Sometimes it is just better to just delete the database and recreate everything than try and work out where the conflict is coming from. A good exercise is to write a script to output the data in the database so that any changes you make can be saved out into a file that can be read in later.

Category Page Workflow

To implement the category pages so that they can be accessed via /rango/category/<category-name-slug>/ we need to make a number of changes and undertake the following steps:

- 1. Import the Page model into rango/views.py.
- 2. Create a new view in rango/views.py called show_category(). The show_category() view will take an additional parameter, category_name_url which will store the encoded category name.
 - We will need helper functions to encode and decode the category_name_url.
- 3. Create a new template, templates/rango/category.html.
- 4. Update Rango's urlpatterns to map the new category view to a URL pattern in rango/urls.py.

We'll also need to update the index() view and index.html template to provide links to the category page view.

Category View

In rango/views.py, we first need to import the Page model. This means we must add the following import statement at the top of the file.

```
from rango.models import Page
```

Next, we can add our new view, show_category().

```
def show_category(request, category_name_slug):
    # Create a context dictionary which we can pass
    # to the template rendering engine.
    context_dict = {}
   try:
        # Can we find a category name slug with the given name?
        # If we can't, the .get() method raises a DoesNotExist exception.
        # So the .get() method returns one model instance or raises an exception.
        category = Category.objects.get(slug=category_name_slug)
        # Retrieve all of the associated pages.
        # Note that filter() will return a list of page objects or an empty list
       pages = Page.objects.filter(category=category)
        # Adds our results list to the template context under name pages.
       context_dict['pages'] = pages
        # We also add the category object from
        # the database to the context dictionary.
        # We'll use this in the template to verify that the category exists.
       context_dict['category'] = category
    except Category.DoesNotExist:
        # We get here if we didn't find the specified category.
        # Don't do anything -
        # the template will display the "no category" message for us.
       context_dict['category'] = None
        context_dict['pages'] = None
    # Go render the response and return it to the client.
   return render(request, 'rango/category.html', context_dict)
```

Our new view follows the same basic steps as our index() view. We first define a context dictionary and then attempt to extract the data from the models, and add the relevant data to the context dictionary. We determine which category by using the value passed as parameter category_name_slug to the show_category() view function. If the category slug is found in the Category model, we can then pull out the associated pages, and add this to the context dictionary, context_dict.

Category Template

Now let's create our template for the new view. In <workspace>/tango_with_django_project/templates/rango/directory, create category.html. In the new file, add the following code.

```
<!DOCTYPE html>
 1
     <html>
 3
    <head>
          <title>Rango</title>
 4
     </head>
 5
     <body>
 6
          <div>
 7
         {% if category %}
 8
              <h1>{{ category.name }}</h1>
 9
              {% if pages %}
10
                   <u1>
11
                   {% for page in pages %}
12
                        \langle li \rangle \langle a \text{ href="} \{ page.url } \} \rangle \{ page.title } \langle /a \rangle \langle /li \rangle
13
                   {% endfor %}
14
                   15
16
              {% else %}
                   <strong>No pages currently in category.
17
              {% endif %}
18
19
          {% else %}
              The specified category does not exist!
20
          {% endif %}
21
         </div>
22
     </body>
23
     </html>
24
```

The HTML code example again demonstrates how we utilise the data passed to the template via its context through the tags {{ }}. We access the category and pages objects, and their fields e.g. category.name and page.url.

If the category exists, then we check to see if there are any pages in the category. If so, we iterate through the pages using the {% for page in pages %} template tags. For each page in the pages list, we present their title and url attributes. This is displayed in an unordered HTML list (denoted by the
 tags). If you are not too familiar with HTML then check out the HTML Tutorial by W3Schools.com¹¹⁶ to learn more about the different tags.

¹¹⁶http://www.w3schools.com/html/

Note on Conditional Template Tags

The Django template conditional tag - $\{\% \text{ if } \%\}$ - is a really neat way of determining the existence of an object within the template's context. Make sure you check the existence of an object to avoid errors.

Placing conditional checks in your templates - like {% if category %} in the example above - also makes sense semantically. The outcome of the conditional check directly affects the way in which the rendered page is presented to the user. Remember, presentational aspects of your Django appls should be encapsulated within templates.

Parameterised URL Mapping

Now let's have a look at how we actually pass the value of the category_name_url parameter to the show_category() function. To do so, we need to modify Rango's urls.py file and update the urlpatterns tuple as follows.

We have added a new path which contains a parameter <slug:category_name_slug>. This indicates to django that we want to match a string which is a slug, and to assign it to category_name_slug. You will notice that this variable name is what we pass through to the view show_category. You can also extract out other variables like strings and integers, see the Django documentation on URL paths¹¹⁷ for more details. If you need to parse more complicated expressions you can use re_path() instead of path() which will allow you to match all sorts of regular (and iregular) expressions. Luckily for us Django provides matches for the most common patterns. <!-> We have added in a rather complex entry that will invoke view.show_category() when the URL pattern r'^category/(?P<category_name_slug>[\w\-]+)/\$' is matched.

There are two things to note here. First we have added a parameter name with in the URL pattern, i.e. <category_name_slug>, which we will be able to access in our view later on. When you create a parameterised URL you need to ensure that the parameters that you include in the URL are declared in the corresponding view. The next thing to note is that the regular expression [\w\-]+) will look for any sequence of alphanumeric characters e.g. a-z, A-Z, or 0-9 denoted by \w and any hyphens (-) denoted by \-, and we can match as many of these as we like denoted by the []+ expression.

The URL pattern will match a sequence of alphanumeric characters and hyphens which are between the rango/category/ and the trailing /. This sequence will be stored in the parameter category_name_slug and passed to views.show_category(). For example, the URL rango/category/python-books/

¹¹⁷https://docs.djangoproject.com/en/2.0/ref/urls/

would result in the category_name_slug having the value, python-books. However, if the URL was rango/category/££££-\$\$\$\$/ then the sequence of characters between rango/category/ and the trailing / would not match the regular expression, and a 404 not found error would result because there would be no matching URL pattern. ->

All view functions defined as part of a Django applications *must* take at least one parameter. This is typically called request - and provides access to information related to the given HTTP request made by the user. When parameterising URLs, you supply additional named parameters to the signature for the given view. That is why our show_category() view was defined as def show_category(request, category_name_slug).

Regex Hell

"Some people, when confronted with a problem, think 'I know, I'll use regular expressions.' Now they have two problems." Jamie Zawinski¹¹⁸

Django's path() method means you can generally avoid Regex Hell - but if you need to use a regular expression this cheat sheet¹¹⁹ is really useful.

Modifying the Index Template

Our new view is set up and ready to go - but we need to do one more thing. Our index page template needs to be updated so that it links to the category pages that are listed. We can update the index.html template to now include a link to the category page via the slug.

¹¹⁸ http://blog.codinghorror.com/regular-expressions-now-you-have-two-problems/

¹¹⁹ http://cheatography.com/davechild/cheat-sheets/regular-expressions/

```
{% if categories %}
        <u1>
            {% for category in categories %}
            <!-- Following line changed to add an HTML hyperlink -->
            <1i>>
            <a href="/rango/category/{{ category.slug }}">{{ category.name }}</a>
            {% endfor %}
        {% else %}
            <strong>There are no categories present.
        {% endif %}
        </div>
        <div>
            <a href="/rango/about/">About Rango</a><br />
            <img src="{% static "images/rango.jpg" %}" alt="Picture of Rango" />
        </div>
    </body>
</html>
```

Again, we used the HTML tag
 to define an unordered list. Within the list, we create a series of list elements (), each of which in turn contains a HTML hyperlink (<a>). The hyperlink has an href attribute, which we use to specify the target URL defined by /rango/category/{{ category.slug }} which, for example, would turn into /rango/category/python-books/ for the category Python Books.

Demo

Let's try everything out now by visiting the Rango homepage. You should see up to five categories on the index page. The categories should now be links. Clicking on Django should then take you to the Django category page, as shown in the figure below. If you see a list of links like Official Django Tutorial, then you've successfully set up the new page.

What happens when you visit a category that does not exist? Try navigating a category which doesn't exist, like /rango/category/computers/. Do this by typing the address manually into your browser's address bar. You should see a message telling you that the specified category does not exist.

The links to Django pages. Note the mouse is hovering over the first link – you can see the corresponding URL for that link at the bottom left of the Google Chrome window.

Exercises

Reinforce what you've learnt in this chapter by trying out the following exercises.

- Update the population script to add some value to the views count for each page.
- Modify the index page to also include the top 5 most viewed pages.
- Include a heading for the "Most Liked Categories" and "Most Viewed Pages".
- Include a link back to the index page from the category page.
- Undertake part three of official Django tutorial¹²⁰ if you have not done so already to reinforce what you've learnt here.

The index page after you complete the exercises, showing the most liked categories and most viewed pages.

Hints

- When updating the population script, you'll essentially follow the same process as you went through in the previous chapter's exercises. You will need to update the data structures for each page, and also update the code that makes use of them.
 - Update the three data structures containing pages for each category python_-pages, django_pages and other_pages. Each page has a title and url they all now need a count of how many views they see, too.
 - Look at how the add_page() function is defined in your population script. Does it allow for you to pass in a views count? Do you need to change anything in this function?
 - Finally, update the line where the add_page() function is *called*. If you called the views count in the data structures views, and the dictionary that represents a page is called p in the context of where add_page() is called, how can you pass the views count into the function?
- Remember to re-run the population script so that the views are updated.
 - You will need to edit both the index view and the index.html template to put the
 most viewed (i.e. popular pages) on the index page.
 - Instead of accessing the Category model, you will have to ask the Page model for the most viewed pages.
 - Remember to pass the list of pages through to the context.
 - If you are not sure about the HTML template code to use, you can draw inspiration from the category.html template code as the markup is essentially the same.

¹²⁰ https://docs.djangoproject.com/en/2.0/intro/tutorial03/

Model Tips

For more tips on working with models you can take a look through the following blog posts:

- 1. Best Practices when working with models¹²¹ by Kostantin Moiseenko. In this post you will find a series of tips and tricks when working with models.
- 2. How to make your Django Models DRYer¹²² by Robert Roskam. In this post you can see how you can use the property method of a class to reduce the amount of code needed when accessing related models.

 $^{^{121}} http://steelkiwi.com/blog/best-practices-working-django-models-python/\\$

 $^{^{122}} https://medium.com/@raiderrobert/make-your-django-models-dryer-4b8d0f3453dd\#.ozrdt3rsm$

As part of the Rango application, we will want to capture new categories and new pages from users. So in this chapter, we will run through how to capture data through web forms. Django comes with some neat form handling functionality, making it a pretty straightforward process to collect information from users and save it to the database via the models. According to Django's documentation on forms¹²³, the form handling functionality allows you to:

- 1. display an HTML form with automatically generated *form widgets* (like a text field or date picker);
- 2. check submitted data against a set of validation rules;
- 3. redisplay a form in case of validation errors; and
- 4. convert submitted form data to the relevant Python data types.

One of the major advantages of using Django's forms functionality is that it can save you a lot of time and hassle creating the HTML forms.

Basic Workflow

The basic steps involved in creating a form and handling user input is as follows.

- 1. If you haven't already got one, create a forms. py file within your Django application's directory to store form-related classes.
- 2. Create a ModelForm class for each model that you wish to represent as a form.
- 3. Customise the forms as you desire.
- 4. Create or update a view to handle the form
 - including *displaying* the form,
 - saving the form data, and
 - *flagging up errors* which may occur when the user enters incorrect data (or no data at all) in the form.
- 5. Create or update a template to display the form.
- 6. Add a urlpattern to map to the new view (if you created a newone).

This workflow is a bit more complicated than previous workflows, and the views that we have to construct have a lot more complexity as well. However, once you undertake the process a few times it will be pretty clear how everything pieces together.

¹²³https://docs.djangoproject.com/en/2.0/topics/forms/

Page and Category Forms

Here, we will implement the necessary infrastructure that will allow users to add categories and pages to the database via forms.

First, create a file called forms.py within the rango application directory. While this step is not absolutely necessary (you could put the forms in the models.py), this makes your codebase tidier and easier to work with.

Creating ModelForm Classes

Within Rango's forms.py module, we will be creating a number of classes that inherit from Django's ModelForm. In essence, a ModelForm¹²⁴ is a *helper class* that allows you to create a Django Form from a pre-existing model. As we've already got two models defined for Rango (Category and Page), we'll create ModelForms for both.

In rango/forms.py add the following code.

```
from django import forms
    from rango.models import Page, Category
 4
    class CategoryForm(forms.ModelForm):
        name = forms.CharField(max_length=128,
 5
                                help_text="Please enter the category name.")
 6
        views = forms.IntegerField(widget=forms.HiddenInput(), initial=0)
        likes = forms.IntegerField(widget=forms.HiddenInput(), initial=0)
 8
9
        slug = forms.CharField(widget=forms.HiddenInput(), required=False)
10
        # An inline class to provide additional information on the form.
11
12
        class Meta:
            # Provide an association between the ModelForm and a model
13
            model = Category
14
            fields = ('name',)
15
16
17
    class PageForm(forms.ModelForm):
        title = forms.CharField(max_length=128,
18
                                 help_text="Please enter the title of the page.")
19
20
        url = forms.URLField(max_length=200,
                              help_text="Please enter the URL of the page.")
21
        views = forms.IntegerField(widget=forms.HiddenInput(), initial=0)
2.2
2.3
24
        class Meta:
```

¹²⁴https://docs.djangoproject.com/en/2.0/topics/forms/modelforms/#modelform

```
# Provide an association between the ModelForm and a model
25
            model = Page
26
27
            # What fields do we want to include in our form?
28
            # This way we don't need every field in the model present.
2.9
            # Some fields may allow NULL values, so we may not want to include them.
30
            # Here, we are hiding the foreign key.
31
            # we can either exclude the category field from the form,
32
            exclude = ('category',)
33
            # or specify the fields to include (i.e. not include the category field)
34
            #fields = ('title', 'url', 'views')
35
```

We need to specify which fields are included on the form, via fields, or specify which fields are to be excluded, via exclude.

Django provides us with a number of ways to customise the forms that are created on our behalf. In the code sample above, we've specified the widgets that we wish to use for each field to be displayed. For example, in our PageForm class, we've defined forms.CharField for the title field, and forms.URLField for url field. Both fields provide text entry for users. Note the max_length parameters we supply to our fields - the lengths that we specify are identical to the maximum length of each field we specified in the underlying data models. Go back to the chapter on models to check for yourself, or have a look at Rango's models.py file.

You will also notice that we have included several IntegerField entries for the views and likes fields in each form. Note that we have set the widget to be hidden with the parameter setting widget=forms.HiddenInput(), and then set the value to zero with initial=0. This is one way to set the field to zero by default. And since the fields will be hidden the user won't be able to enter a value for these fields.

However, as you can see in the PageForm, despite the fact that we have a hidden field, we still need to include the field in the form. If in fields we excluded views, then the form would not contain that field (despite it being specified) and so the form would not return the value zero for that field. This may raise an error depending on how the model has been set up. If in the model we specified that the default=0 for these fields then we can rely on the model to automatically populate field with the default value - and thus avoid a not null error. In this case, it would not be necessary to have these hidden fields. We have also included the field slug in the CategoryForm, and set it to use the widget=forms.HiddenInput(), but rather than specifying an initial or default value, we have said the field is not required by the form. This is because our model will be responsible on save() for populating this field. Essentially, you need to be careful when you define your models and forms to make sure that the form is going to contain and pass on all the data that is required to populate your model correctly.

Besides the CharField and IntegerField widgets, many more are available for use. As an example, Django provides EmailField (for e-mail address entry), ChoiceField (for radio input buttons), and DateField (for date/time entry). There are many other field types you can use, which perform error

checking for you (e.g. is the value provided a valid integer?).

Perhaps the most important aspect of a class inheriting from ModelForm is the need to define which model we're wanting to provide a form for. We take care of this through our nested Meta class. Set the model attribute of the nested Meta class to the model you wish to use. For example, our CategoryForm class has a reference to the Category model. This is a crucial step enabling Django to take care of creating a form in the image of the specified model. It will also help in handling flagging up any errors along with saving and displaying the data in the form.

We also use the Meta class to specify which fields that we wish to include in our form through the fields tuple. Use a tuple of field names to specify the fields you wish to include.

More about Forms

Check out the official Django documentation on forms¹²⁵ for further information about the different widgets and how to customise forms.

Creating an Add Category View

With our CategoryForm class now defined, we're now ready to create a new view to display the form and handle the posting of form data. To do this, add the following code to rango/views.py.

```
#Add this import at the top of the file
from rango.forms import CategoryForm
def add_category(request):
    form = CategoryForm()
   # A HTTP POST?
    if request.method == 'POST':
        form = CategoryForm(request.POST)
        # Have we been provided with a valid form?
        if form.is_valid():
            # Save the new category to the database.
            form.save(commit=True)
            # Now that the category is saved
            # We could give a confirmation message
            # But since the most recent category added is on the index page
            # Then we can direct the user back to the index page.
            return index(request)
```

¹²⁵https://docs.djangoproject.com/en/2.0/ref/forms/

```
# The supplied form contained errors -
# just print them to the terminal.
print(form.errors)

# Will handle the bad form, new form, or no form supplied cases.
# Render the form with error messages (if any).
return render(request, 'rango/add_category.html', {'form': form})
```

The new add_category() view adds several key pieces of functionality for handling forms. First, we create a CategoryForm(), then we check if the HTTP request was a POST i.e. if the user submitted data via the form. We can then handle the POST request through the same URL. The add_category() view function can handle three different scenarios:

- showing a new, blank form for adding a category;
- saving form data provided by the user to the associated model, and rendering the Rango homepage; and
- if there are errors, redisplay the form with error messages.

GET and POST

What do we mean by GET and POST? They are two different types of *HTTP requests*.

- A HTTP GET is used to request a representation of the specified resource. In other words, we use a HTTP GET to retrieve a particular resource, whether it is a webpage, image or other file.
- In contrast, a HTTP POST *submits data from the client's web browser to be processed.*This type of request is used for example when submitting the contents of a HTML form.
- Ultimately, a HTTP POST may end up being programmed to create a new resource (e.g. a new database entry) on the server. This can later be accessed through a HTTP GET request.
- Check out the w3schools page on GET vs. POST 126 for more details.

Django's form handling machinery processes the data returned from a user's browser via a HTTP POST request. It not only handles the saving of form data into the chosen model, but will also automatically generate any error messages for each form field (if any are required). This means that Django will not store any submitted forms with missing information that could potentially cause problems for your database's referential integrity¹²⁷. For example, supplying no value in the category name field will return an error, as the field cannot be blank.

 $^{^{126}} http://www.w3schools.com/tags/ref_httpmethods.asp$

¹²⁷https://en.wikipedia.org/wiki/Referential_integrity

You'll notice from the line in which we call render() that we refer to a new template called add_category.html. This will contain the relevant Django template code and HTML for the form and page.

Creating the Add Category Template

Create the file templates/rango/add_category.html. Within the file, add the following HTML markup and Django template code.

```
<!DOCTYPE html>
 1
 2
    <html>
        <head>
 3
             <title>Rango</title>
 4
        </head>
 5
 6
        <body>
             <h1>Add a Category</h1>
8
 9
             <div>
                 <form id="category_form" method="post" action="/rango/add_category/">
10
                      {% csrf_token %}
11
                     {% for hidden in form.hidden_fields %}
12
                          {{ hidden }}
13
                     {% endfor %}
14
                     {% for field in form.visible_fields %}
                          {{ field.errors }}
16
                          {{ field.help_text }}
17
                          {{ field }}
18
                      {% endfor %}
19
20
                      <input type="submit" name="submit" value="Create Category" />
                 </form>
21
             </div>
22
23
        </body>
    </html>
24
```

You can see that within the <code><body></code> of the HTML page we placed a <code><form></code> element. Looking at the attributes for the <code><form></code> element, you can see that all data captured within this form is sent to the URL <code>/rango/add_category/</code> as a HTTP POST request (the <code>method</code> attribute is case insensitive, so you can do <code>POST</code> or <code>post</code> - both provide the same functionality). Within the form, we have two for loops:

- one controlling *hidden* form fields, and
- the other *visible* form fields.

The visible fields i.e. those that will be displayed to the user, are controlled by the fields attribute within your ModelForm Meta class. These loops produce HTML markup for each form element. For visible form fields, we also add in any errors that may be present with a particular field and help text that can be used to explain to the user what he or she needs to enter.

Hidden Fields

The need for hidden as well as visible form fields is necessitated by the fact that HTTP is a stateless protocol. You can't persist state between different HTTP requests that can make certain parts of web applications difficult to implement. To overcome this limitation, hidden HTML form fields were created which allow web applications to pass important information to a client (which cannot be seen on the rendered page) in a HTML form, only to be sent back to the originating server when the user submits the form.

Cross Site Request Forgery Tokens

You should also take note of the code snippet {% csrf_token %}. This is a *Cross-Site Request Forgery (CSRF) token*, which helps to protect and secure the HTTP POST action that is initiated on the subsequent submission of a form. *The Django framework requires the CSRF token to be present. If you forget to include a CSRF token in your forms, a user may encounter errors when he or she submits the form.* Check out the official Django documentation on CSRF tokens¹²⁸ for more information about this.

Mapping the Add Category View

Now we need to map the add_category() view to a URL. In the template we have used the URL /rango/add_category/ in the form's action attribute. We now need to create a mapping from the URL to the View. In rango/urls.py modify the urlpatterns

```
urlpatterns = [
          path('', views.index, name='index'),
          path('about/', views.about, name='about'),
          path('category/<slug:category_name_slug>/', views.show_category, name='show_catego\
ry'),
     path('add_category/', views.add_category, name='add_category'),
```

Ordering doesn't necessarily matter in this instance. However, take a look at the official Django documentation on how Django processes a request¹²⁹ for more information. The URL for adding a category is /rango/add_category/.

¹²⁸https://docs.djangoproject.com/en/2.0/ref/csrf/

¹²⁹ https://docs.djangoproject.com/en/2.0/topics/http/urls/#how-django-processes-a-request

Modifying the Index Page View

As a final step let's put a link on the index page so that we can easily add categories. Edit the template rango/index.html and add the following HTML hyperlink in the <div> element with the about link.

Add a New Category

Demo

Now let's try it out! Start or restart your Django development server, and then point your web browser to Rango at http://127.0.0.1:8000/rango/. Use your new link to jump to the Add Category page, and try adding a category. The figure below shows screenshots of the Add Category and Index Pages.

Missing Categories

If you add a number of categories, they will not always appear on the index page. This is because we are only showing the top five categories on the index page. If you log into the Admin interface, you should be able to view all the categories that you have entered.

Another way to get some confirmation that the category is being added is to update the add_category() method in rango/views.py and change the line form.save(commit=True) to be cat = form.save(commit=True). This will give you a reference to an instance of the category object created by the form. You can then print the category to console (e.g. print(cat, cat.slug)).

Cleaner Forms

Recall that our Page model has a url attribute set to an instance of the URLField type. In a corresponding HTML form, Django would reasonably expect any text entered into a url field to be a correctly formatted, complete URL. However, users can find entering something like http://www.url.com to be cumbersome - indeed, users may not even know what forms a correct URL¹³⁰!

¹³⁰https://support.google.com/webmasters/answer/76329?hl=en

URL Checking

Most modern browsers will now check to make sure that the URL is well-formed for you, so this example will only work on older browsers. However, it does show you how to clean the data before you try to save it to the database. If you don't have an old browser to try this example (in case you don't believe it), try changing the URLField to a CharField. The rendered HTML will then not instruct the browser to perform the checks on your behalf, and the code you implemented will be executed.

In scenarios where user input may not be entirely correct, we can *override* the clean() method implemented in ModelForm. This method is called upon before saving form data to a new model instance, and thus provides us with a logical place to insert code which can verify - and even fix any form data the user inputs. We can check if the value of url field entered by the user starts with http:// - and if it doesn't, we can prepend http:// to the user's input.

```
class PageForm(forms.ModelForm):
    ...

def clean(self):
    cleaned_data = self.cleaned_data
    url = cleaned_data.get('url')

# If url is not empty and doesn't start with 'http://',
    # then prepend 'http://'.
    if url and not url.startswith('http://'):
        url = 'http://' + url
        cleaned_data['url'] = url

        return cleaned_data
```

Within the clean() method, a simple pattern is observed which you can replicate in your own Django form handling code.

- 1. Form data is obtained from the ModelForm dictionary attribute cleaned_data.
- 2. Form fields that you wish to check can then be taken from the cleaned_data dictionary. Use the .get() method provided by the dictionary object to obtain the form's values. If a user does not enter a value into a form field, its entry will not exist in the cleaned_data dictionary. In this instance, .get() would return None rather than raise a KeyError exception. This helps your code look that little bit cleaner!
- 3. For each form field that you wish to process, check that a value was retrieved. If something was entered, check what the value was. If it isn't what you expect, you can then add some logic to fix this issue before *reassigning* the value in the cleaned_data dictionary.
- 4. You *must* always end the clean() method by returning the reference to the cleaned_data dictionary. Otherwise the changes won't be applied.

This trivial example shows how we can clean the data being passed through the form before being stored. This is pretty handy, especially when particular fields need to have default values - or data within the form is missing, and we need to handle such data entry problems.

Clean Overrides

Overriding methods implemented as part of the Django framework can provide you with an elegant way to add that extra bit of functionality for your application. There are many methods which you can safely override for your benefit, just like the clean() method in ModelForm as shown above. Check out the Official Django Documentation on Models¹³¹ for more examples on how you can override default functionality to slot your own in.

Exercises

Now that you've worked through the chapter, consider the following questions, and how you could solve them.

- What would happen if you don't enter in a category name on the add category form?
- What happens when you try to add a category that already exists?
- What happens when you visit a category that does not exist? A hint for a potential solution to solving this problem can be found below.
- In the section above where we implemented our ModelForm classes, we repeated the max_length values for fields that we had previously defined in the models chapter. This is bad practice as we are *repeating ourselves!* How can you refactor your code so that you are *not* repeating the max_length values?
- If you have not done so already undertake part four of the official Django Tutorial¹³² to reinforce what you have learnt here.
- Now let users add pages to each category, see below for some example code and hints.

Creating an Add Pages View, Template and URL Mapping

A next logical step would be to allow users to add pages to a given category. To do this, repeat the same workflow above but for adding pages.

- create a new view, add_page(),
- create a new template, rango/add_page.html,
- add a URL mapping, and
- update the category page/view to provide a link from the category add page functionality.

To get you started, here is the code for the add_page() view function.

 $^{^{131}} https://docs.djangoproject.com/en/2.0/topics/db/models/\#overriding-predefined-model-methods$

¹³²https://docs.djangoproject.com/en/2.0/intro/tutorial04/

```
from rango.forms import PageForm
def add_page(request, category_name_slug):
       category = Category.objects.get(slug=category_name_slug)
    except Category.DoesNotExist:
       category = None
    form = PageForm()
    if request.method == 'POST':
        form = PageForm(request.POST)
        if form.is_valid():
            if category:
                page = form.save(commit=False)
                page.category = category
                page.views = ∅
                page.save()
                return show_category(request, category_name_slug)
        else:
            print(form.errors)
   context_dict = {'form':form, 'category': category}
    return render(request, 'rango/add_page.html', context_dict)
```

Hints

To help you with the exercises above, the following hints may be of some use to you.

• In the add_page.html template you can access the slug with {{ category.slug }} because the view passes the category object through to the template via the context dictionary.

- Ensure that the link only appears when the requested category exists with or without pages. i.e. in the template check with {% if cat %} {% else %} A category by this name does not exist {% endif %}.
- Update Rango's category.html template with a new hyperlink with a line break immediately following it: Add Page

- Make sure that in your add_page.html template that the form posts to /rango/category/{{ category.slug }}/add_page/.
- Update rango/urls.py with a URL mapping (/rango/category/<category_name_-slug>/add_page/) to handle the above link.
- You can avoid the repetition of max_length parameters through the use of an additional attribute in your Category class. This attribute could be used to store the value for max_length, and then be referenced where required.

If you get really stuck, you can always check out our code on GitHub¹³³.

¹³³https://github.com/leifos/tango_with_django_2

So far, we've created several HTML templates for different pages within our Rango application. As you created each additional template, you may have noticed that a lot of the HTML code is repeated. Anytime you repeat similar code, you are violating the DRY Principle¹³⁴ - which states: DO NOT REPEAT YOURSELF! You might have also noticed that the way we have been referring to different pages using *hard coded* URL paths. This is bad practice - names will invariably change. Taken together, repetition and hard coding will result in a maintainence nightmare, because if we want to make a change to the general site structure or change a URL path, you will have to modify all the templates which has the URL or where the structure changes. This might be tractable if your site has a few pages, but always think, what if my site had hundreds or millions - how long would it take then? How likely are mistakes?

Luckily for us Django developers have already thought about how to solve such problems and provided solutions. In this chapter, we will use *template inheritance* to overcome the first problem, and the *URL template tag* to solve the second problem. We will start with addressing the latter problem first.

Using Relative URLs in Templates

So far, we have been directly coding the URL of the page or view we want to show within the template, i.e. About. This kind of hard coding of URLs means that if we change our URL mappings in urls.py, then we will have to also change all of these URL references. The preferred way is to use the template tag url to look up the URL in the urls.py files and dynamically insert the URL path.

It's pretty simple to include relative URLs in your templates. To refer to the *About* page, we would insert the following line into our templates:

```
<a href="{% url 'about' %}">About</a>
```

The Django template engine will look up any urls.py module for a URL pattern with the attribute name set to about (name='about'), and then reverse match the actual URL. This means if we change the URL mappings in urls.py, we don't have to go through all our templates and update them.

One can also reference a URL pattern without a specified name, by referencing the view directly as shown below.

 $^{^{134}} https://en.wikipedia.org/wiki/Don\%27t_repeat_yourself$

```
<a href="{% url 'rango.views.about' %}">About</a>
```

In this example, we must ensure that the apprango has the view about, contained within its views.py module.

In your app's index.html template, you will notice that you have a parameterised URL pattern (the show_category URL/view takes the category.slug as a parameter). To handle this, you can pass the url template tag the name of the URL/view and the slug within the template, as follows:

Before you run off to update all the URLs in all your templates with relative URLs, we need to restructure and refactor our templates by using inheritance to remove repetition.

URLs and Multiple Django Apps

This book focuses on the development on a single Django app, Rango. However, you may find yourself working on a Django project with multiple apps being used at once. This means that you could literally have hundreds of potential URLs with which you may need to reference. This scenario begs the question *how can we organise these URLs?* Two apps may have a view of the same name, meaning a potential conflict would exist.

Django provides the ability to *namespace* URL configuration modules¹³⁵ (e.g. urls.py) for each individual app that you employ in your project. Simply adding an app_name variable to your app's urls.py module is enough. The example below specifies the namespace for the Rango app to be rango.

```
from django.conf.urls import url
from rango import views

app_name = 'rango'
urlpatterns = [
    path('', views.index, name='index'),

path('about/', views.about, name='about'), path('category/<slug:category_name_-slug>/add_page/',

views.add_page, name='add_page'),

...

i views.add_page, name='add_page'),

...

j
```

Adding an app_name variable would then mean that any URL you reference from the rango app could be done so like:

```
<a href="{% url 'rango:about' %}">About</a>
```

where the colon in the url command separates the namespace from the URL name. Of course, this is an advanced feature for when multiple apps are in presence - but it is a useful trick to know when things start to scale up.

Dealing with Repetition

While pretty much every professionally made website that you use will have a series of repeated components (such as page headers, sidebars, and footers, for example), repeating the HTML for each of these repeating components is not a particularly wise way to handle this. What if you wanted to change part of your website's header? You'd need to go through *every* page and change each copy of the header to suit. That could take a long time - and allow the possibility for human error to creep in

 $^{^{135}} https://docs.djangoproject.com/en/2.0/topics/http/urls/\#url-namespaces/specific com/en/2.0/topics/http/urls/#url-namespaces/specific com/en/2.0/topics/http/urls/http/urls/http/urls/http/urls/http/urls/http/urls/http/urls/http/urls/http$

Instead of spending (or wasting!) large amounts of time copying and pasting your HTML markup, we can minimise repetition in Rango's codebase by employing *template inheritance* provided by Django's template language.

The basic approach to using inheritance in templates is as follows.

- 1. Identify the reoccurring parts of each page that are repeated across your application (i.e. header bar, sidebar, footer, content pane). Sometimes, it can help to draw up on paper the basic structure of your different pages to help you spot what components are used in common.
- 2. In a *base template*, provide the skeleton structure of a basic page, along with any common content (i.e. the copyright notice that goes in the footer, the logo and title that appears in the section). Then, define a number of *blocks* which are subject to change depending on which page the user is viewing.
- 3. Create specific templates for your app's pages all of which inherit from the base template and specify the contents of each block.

Reoccurring HTML and The Base Template

Given the templates that we have created so far, it should be pretty obvious that we have been repeating a fair bit of HTML code. Below, we have abstracted away any page specific details to show the skeleton structure that we have been repeating within each template.

```
<!DOCTYPE html>
 1
    {% load staticfiles %}
 2
 3
    <html>
 4
         <head lang="en">
 5
             <meta charset="UTF-8" />
 6
             <title>Rango</title>
         </head>
 8
 9
         <body>
10
             <!-- Page specific content goes here -->
11
         </body>
    </html>
12
```

For the time being, let's make this simple HTML page our app's base template. Save this markup in base.html within the templates/rango/directory (e.g. templates/rango/base.html).

DOCTYPE goes First!

Remember that the <!DOCTYPE html> declaration *always needs to be placed on the first line* of your template. Not having a document type declaration¹³⁶ on line one may mean that the resultant page generated from your template will not comply with W3C HTML guidelines¹³⁷.

¹³⁶https://en.wikipedia.org/wiki/Document_type_declaration

¹³⁷https://www.w3.org/standards/webdesign/htmlcss

Template Blocks

Now that we've created our base template, we can add template tags to denote what parts of the template can be overridden by templates that inherit from it. To do this we will be using the block tag. For example, we can add a body_block to the base template in base.html as follows:

```
<!DOCTYPE html>
 1
    {% load staticfiles %}
 3
    <html>
 4
         <head lang="en">
 5
             <meta charset="UTF-8" />
 6
 7
             <title>Rango</title>
 8
         </head>
         <body>
9
             {% block body_block %}
10
             {% endblock %}
11
         </body>
12
13
    </html>
```

Recall that standard Django template commands are denoted by {% and %} tags. To start a block, the command is {% block <NAME> %}, where <NAME> is the name of the block you wish to create. You must also ensure that you close the block with the {% endblock %} command, again enclosed within Django template tags.

You can also specify *default content* for your blocks, which will be used if no inheriting template defines the given block (see further down). Specifying default content can be easily achieved by adding HTML markup between the {% block %} and {% endblock %} template commands, just like in the example below.

```
{% block body_block %}
    This is body_block's default content.
{% endblock %}
```

When we create templates for each page, we will inherit from rango/base.html and override the contents of body_block. However, you can place as many blocks in your templates as you so desire. For example, you could create a block for the page title, a block for the footer, a block for the sidebar, and more. Blocks are a really powerful feature of Django's templating system, and you can learn more about them check on Django's official documentation on templates¹³⁸.

¹³⁸https://docs.djangoproject.com/en/1.9/topics/templates/

Extract Common Structures

You should always aim to extract as much reoccurring content for your base templates as possible. While it may be a hassle to do, the time you will save in maintenance will far outweigh the initial overhead of doing it up front.

Thinking hurts, but it is better than doing lots of grunt work!

Abstracting Further

Now that you have an understanding of blocks within Django templates, let's take the opportunity to abstract our base template a little bit further. Reopen the rango/base.html template and modify it to look like the following.

```
<!DOCTYPE html>
 1
2
    {% load staticfiles %}
3
    <html>
 4
5
        <head>
            <title>
6
                Rango -
8
                {% block title_block %}
                   - How to Tango with Django!
9
                {% endblock %}
10
11
            </title>
        </head>
12
13
        <body>
            <div>
14
15
                {% block body_block %}
16
                {% endblock %}
            </div>
17
            <hr />
18
19
            <div>
                <u1>
20
21
                    <a href="{% url 'add_category' %}">Add New Category</a>
                    <a href="{% url 'about' %}">About</a>
2.2.
                    <a href="{% url 'index' %}">Index</a>
23
24
                </div>
25
26
        </body>
    </html>
27
```

From the example above, we have introduced two new features into the base template.

• The first is a template block called title_block. This will allow us to specify a custom page title for each page inheriting from our base template. If an inheriting page does not override the block, then the title_block defaults to How to Tango with Django!, resulting in a complete title of Rango - How to Tango with Django!. Look at the contents of the <title> tag in the above template to see how this works.

• We have also included the list of links from our current index.html template and placed them into a HTML <div> tag underneath our body_block block. This will ensure the links are present across all pages inheriting from the base template. The links are preceded by a *horizontal rule* (<hr />) which provides a visual separation for the user between the content of the body_block block and the links.

Template Inheritance

Now that we've created a base template with blocks, we can now update all the templates we have created so that they inherit from the base template. Let's start by refactoring the template rango/category.html.

To do this, first remove all the repeated HTML code leaving only the HTML and template tags/commands specific to the page. Then at the beginning of the template add the following line of code:

```
{% extends 'rango/base.html' %}
```

The extends command takes one parameter - the template that is to be extended/inherited from (i.e. rango/base.html). The parameter you supply to the extends command should be relative from your project's templates directory. For example, all templates we use for Rango should extend from rango/base.html, not base.html. We can then further modify the category.html template so it looks like the following complete example.

```
{% extends 'rango/base.html' %}
 1
    {% load staticfiles %}
    {% block title_block %}
 4
       {{ category.name }}
 5
    {% endblock %}
 6
    {% block body_block %}
8
        {% if category %}
9
             <h1>{{ category.name }}</h1>
10
             {% if pages %}
12
                 <u1>
13
```

```
14
               {% for page in pages %}
                    <a href="{{ page.url }}">{{ page.title }}</a>
15
               {% endfor %}
16
               17
            {% else %}
18
                <strong>No pages currently in category.
19
20
            <a href="{% url 'add_page' category.slug %}">Add a Page</a>
21
        {% else %}
22
           The specified category does not exist!
23
24
        {% endif %}
    {% endblock %}
25
```

Loading staticfiles

You'll need to make sure you add {% load staticfiles %} to the top of each template that makes use of static media. If you don't, you'll get an error! Django template modules must be imported individually for each template that requires them. If you've programmed before, this works somewhat differently from object orientated programming languages such as Java, where imports cascade down inheriting classes. Notice how we used the url template tag to refer to rango/<category-name>/add_page/ URL pattern. The category.slug is passed through as a parameter to the url template tag and Django's Template Engine will produce the correct URL for us.

Now that we inherit from rango/base.html, the category.html template is much cleaner extending the title_block and body_block blocks. You don't need a well-formatted HTML document because base.html provides all the groundwork for you. All you're doing is plugging in additional content to the base template to create the complete, rendered HTML document that is sent to the client's browser. This rendered HTML document will then conform to the standards, containing components such as the document type declaration on the first line.

More about Templates

Here we have shown how we can minimise the repetition of structure HTML in our templates. However, the Django templating language is very powerful, and even lets you create your own template tags.

Templates can also be used to minimise code within your application's views. For example, if you wanted to include the same database driven content on each page of your application, you could construct a template that calls a specific view to handle the repeating portion of your app's pages. This then saves you from having to call the Django ORM functions that gather the required data for the template in every view that renders it.

If you haven't already done so, now would be a good time to read through the official Django documentation on templates¹³⁹.

¹³⁹ https://docs.djangoproject.com/en/2.0/topics/templates/

Exercises

Now that you've worked through this chapter, there are a number of exercises that you can work through to reinforce what you've learnt regarding Django and templating.

- Update all other previously defined templates in the Rango app to extend from the new base.html template. Follow the same process as we demonstrated above. Once completed, your templates should all inherit from base.html.
- While you're at it, make sure you remove the links from our index.html template. We
 don't need them anymore! You can also remove the link to Rango's homepage within
 the about.html template.
- When you refactor the index.html keep the images that are served up from the static files and media server.
- Update all references to Rango URLs by using the url template tag. You can also do this in your views.py module too check out the reverse() helper function¹⁴⁰.

Hints

- Start refactoring the about . html template first.
- Update the title_block then the body_block in each template.
- Have the development server running and check the page as you work on it. Don't change the whole page to find it doesn't work. Changing things incrementally and testing those changes as you go is a much safer solution.
- To reference the links to category pages, you can use the following template code, paying particular attention to the Django template {% url %} command.

```
<a href="{% url 'show_category' category.slug %}">{{ category.name }}</a>
```

The render() Method and the request Context

When writing views we have used a number of different methods, the preferred way is to use the Django shortcut method render(). The render() method requires that you pass through the request as the first argument. The request context houses a lot of information regarding the session, the user, etc, see the Official Django Documentation on Request objects¹⁴¹. By passing the request through to the template mean that you will also have access to such information when creating templates. In the next chapter we will access information about the user - but for now check through all of your

¹⁴⁰https://docs.djangoproject.com/en/2.0/ref/urlresolvers/#reverse

 $^{^{141}} https://docs.djangoproject.com/en/2.0/ref/request-response/\#httprequest-objects$

views and make sure that they have been implemented using the render() method. Otherwise, your templates won't have the information we need later on.

Render and Context

As a quick example of the checks you must carry out, have a look at the <code>about()</code> view. Initially, this was implemented with a hard-coded string response, as shown below. Note that we only send the string - we don't make use of the request passed as the request parameter.

To employ the use of a template, we call the render() function and pass through the request object. This will allow the template engine to access information such as the request type (e.g. GET/POST), and information relating to the user's status (have a look at Chapter 9).

```
def about(request):
    # prints out whether the method is a GET or a POST
    print(request.method)
    # prints out the user name, if no one is logged in it prints `AnonymousUser`
    print(request.user)
    return render(request, 'rango/about.html', {})
```

Remember, the last parameter of render() is the context dictionary with which you can use to pass additional data to the Django template engine. As we have no additional data to give to the template, we pass through an empty dictionary, {}.

Custom Template Tags

It would be nice to show the different categories that users can browse through in the sidebar on each page. Given what we have learnt so far, we could do the following:

- in the base . html template, we could add some code to display an item list of categories; and
- within each view, we could access the Category object, get all the categories, and return that
 in the context dictionary.

However, this is a pretty nasty solution because we will need to include the same code in all views. A DRYer¹⁴² solution would be to create custom template tags that are included in the template, and which can request *their own* data.

¹⁴²https://en.wikipedia.org/wiki/Don%27t_repeat_yourself

Using Template Tags

Create a directory rango/templatetags, and create two new modules within it. One must be called __init__.py, and this will be kept blank. Name the second module rango_template_tags.py. Add the following code to this second module.

```
from django import template
from rango.models import Category

register = template.Library()

register.inclusion_tag('rango/cats.html')

def get_category_list():
    return {'cats': Category.objects.all()}
```

From this code snippet, you can see a new method called <code>get_category_list()</code>. This method returns a list of categories - but is mashed up with the template <code>rango/cats.html</code> (as can be seen from the <code>register.inclusion_tag()</code> decorator). You can now create this template file, and add the following HTML markup:

```
<u1>
1
2
  {% if cats %}
3
      {% for c in cats %}
          <a href="{% url 'rango:show_category' c.slug %}">{{ c.name }}</a>
4
5
      {% endfor %}
  {% else %}
6
      <strong>There are no categories present.</strong>
7
  {% endif %}
8
```

To use the template tag in your base.html template, first load the custom template tag by including the command {% load rango_template_tags %} at the top of the base.html template. You can then create a new block to represent the sidebar - and we can call our new template tag with the following code.

```
<div>
     {% block sidebar_block %}
         {% get_category_list %}
      {% endblock %}
</div>
```

Try it out. Now all pages that inherit from base.html will also include the list of categories (which we will move to the side later on).

Restart the Server!

You'll need to restart the Django development server (or ensure it restarted itself) every time you modify template tags. If the server doesn't restart, Django won't register the tags.

Parameterised Template Tags

We can also *parameterise* the template tags we create, allowing for greater flexibility. As an example, we'll use parameterisation to highlight which category we are looking at when visiting its page. Adding in a parameter is easy - we can update the <code>get_category_list()</code> method as follows.

Note the inclusion of the cat parameter to <code>get_category_list()</code>, which is optional - and if you don't pass in a category, <code>None</code> is used as the subsequent value.

We can then update our base.html template which makes use of the custom template tag to pass in the current category - but only if it exists.

```
<div>
     {% block sidebar_block %}
          {% get_category_list category %}
      {% endblock %}
</div>
```

We can also now update the cats.html template, too.

In the template, we check to see if the category being displayed is the same as the category being passed through during the for loop (i.e. c == act_cat). If so, we highlight the category name by making it **bold** through use of the tag.

Summary

In this chapter, we showed how we can:

- reduce coupling between URLs and templates by using the url template tag to point to relative URLs;
- reduced the amount of boilerplate code by using template inheritance; and
- avoid repetitive code appearing in views by creating custom templates tags.

Taken together, your template code should be much cleaner and easier to maintain. Of course, Django templates offer a lot more functionality - find out more by visiting the Django documentation on templates¹⁴³.

¹⁴³https://docs.djangoproject.com/en/2.0/ref/templates/

In this chapter, we will be touching on the basics of handling *sessions* and storing *cookies*. Both go hand in hand with each other, and provide the basis for persisting the current state of the application. In the previous chapter, the Django framework used sessions and cookies to handle the login and logout functionality. However, all this was done behind the scenes. Here we will explore exactly what is going on under the hood, and how we can use cookies ourselves for other purposes.

Cookies, Cookies Everywhere!

Whenever a request to a website is made, the webserver returns the content of the requested page. In addition, one or more cookies may also be sent as part of the request. Consider a cookie as a small piece of information sent from the server to the client. When a request is about to be sent, the client checks to see if any cookies that match the address of server exist on the client. If so, they are included in the request. The server can then interpret the cookies as part of the request's context and generate a response to suit.

As an example, you may login to a site with a particular username and password. When you have been authenticated, a cookie may be returned to your browser containing your username, indicating that you are now logged into the site. At every request, this information is passed back to the server where your login information is used to render the appropriate page - perhaps including your username in particular places on the page. Your session cannot last forever, however - cookies *have* to expire at some point in time - they cannot be of infinite length. A Web application containing sensitive information may expire after only a few minutes of inactivity. A different Web application with trivial information may expire half an hour after the last interaction - or even weeks into the future.

Cookie Origins

The term *cookie* wasn't actually derived from the food that you eat, but from the term *magic cookie*, a packet of data a program receives and sends again unchanged. In 1994, *MCI* sent a request to *Netscape Communications* to implement a way of implementing persistence across HTTP requests. This was in response to their need to reliably store the contents of a user's virtual shopping basket for an e-commerce solution they were developing. Netscape programmer Lou Montulli took the concept of a magic cookie and applied it to Web communications.

You can find out more about cookies and their history on Wikipedia¹⁴⁴. Of course, with such a great idea came a software patent - and you can read US patent 5774670¹⁴⁵ that was submitted by Montulli himself.

¹⁴⁴http://en.wikipedia.org/wiki/HTTP_cookie#History

 $^{^{145}}http://patft.uspto.gov/netacgi/nph-Parser?Sect1=PTO1\&Sect2=HITOFF\&d=PALL\&p=1\&u=\%2Fnetahtml\%2FPTO\%2Fsrchnum.htm\&r=1\&f=G\&l=50\&s1=5774670.PN.\&OS=PN/5774670\&RS=PN/5774670$

The passing of information in the form of cookies can open up potential security holes in your Web application's design. This is why developers of Web applications need to be extremely careful when using cookies. When using cookies, a designer must always ask himself or herself: *does the information you want to store as a cookie really need to be sent and stored on a client's machine?* In many cases, there are more secure solutions to the problem. Passing a user's credit card number on an e-commerce site as a cookie for example would be highly insecure. What if the user's computer is compromised? A malicious program could take the cookie. From there, hackers would have his or her credit card number - all because your Web application's design is fundamentally flawed. This chapter examines the fundamental basics of client-side cookies - and server-side session storage for Web applications.

A screenshot of the BBC News website (hosted in the United Kingdom) with the cookie warning message presented at the top of the page.

Cookies in the EU

In 2011, the European Union (EU) introduced an EU-wide 'cookie law', where all hosted sites within the EU should present a cookie warning message when a user visits the site for the first time. The figure above demonstrates such a warning on the BBC News website. You can read about the law here¹⁴⁶.

If you are developing a site, you'll need to be aware of this law, and other laws especially regarding accessibility and more recently explainability.

Sessions and the Stateless Protocol

All correspondence between Web browsers (clients) and servers is achieved through the HTTP protocol¹⁴⁷. As previously mentioned, HTTP is a stateless protocol¹⁴⁸. This means that a client computer running a Web browser must establish a new network connection (a TCP¹⁴⁹ connection) to the server each time a resource is requested (HTTP GET) or sent (HTTP POST) ¹⁵⁰.

Without a persistent connection between the client and server, the software on both ends cannot simply rely on connections alone to *hold session state*. For example, the client would need to tell the server each time who is logged on to the Web application on a particular computer. This is known as a form of *dialogue* between the client and server, and is the basis of a *session* - a semi-permanent

 $^{^{146}} https://ico.org.uk/for-organisations/guide-to-pecr/cookies-and-similar-technologies/$

 $^{^{147}} http://en.wikipedia.org/wiki/Hypertext_Transfer_Protocol$

¹⁴⁸http://en.wikipedia.org/wiki/Stateless_protocol

¹⁴⁹https://en.wikipedia.org/wiki/Transmission_Control_Protocol

¹⁵⁰The latest version of the HTTP standard HTTP 1.1 actually supports the ability for multiple requests to be sent in one TCP network connection. This provides huge improvements in performance, especially over high-latency network connections (such as via a traditional dial-up modem and satellite). This is referred to as *HTTP pipelining*, and you can read more about this technique on Wikipedia.

exchange of information¹⁵¹. Being a stateless protocol, HTTP makes holding session state pretty challenging, but there are luckily several techniques we can use to circumnavigate this problem.

The most commonly used way of holding state is through the use of a *session ID* stored as a cookie on a client's computer. A session ID can be considered as a token (a sequence of characters, or a *string*) to identify a unique session within a particular Web application. Instead of storing all kinds of information as cookies on the client (such as usernames, names, or passwords), only the session ID is stored, which can then be mapped to a data structure on the Web server. Within that data structure, you can store all of the information you require. This approach is a **much more secure** way to store information about users. This way, the information cannot be compromised by a insecure client or a connection which is being snooped.

If you're using a modern browser that's properly configured, it'll support cookies. Pretty much every website that you visit will create a new *session* for you when you visit. You can see this for yourself now – check out the screenshot below. For Google Chrome, you can view cookies for the currently open website by accessing Chrome's Developer Tools, by accessing *Chrome Settings > More Tools > Developer Tools*. When the Developer Tools pane opens, click the *Application* tab, and look for *Cookies* down the left hand side, within the *Storage* menu. If you're running this with a Rango page open, you should then hopefully see a cookie called sessionid. The sessionid cookie contains a series of letters and numbers that Django uses to uniquely identify your computer with a given session. With this session ID, all your session details can be accessed – but they are only stored on the *server side*.

A screenshot of Google Chrome's Developer Tools with the sessionid cookie highlighted.

Without Cookies

An alternative way of persisting state information *without cookies* is to encode the Session ID within the URL. For example, you may have seen PHP pages with URLs like this one: http://www.site.com/index.php?sessid=someseeminglyrandomandlongstring1234. This means you don't need to store cookies on the client machine, but the URLs become pretty ugly. These URLs go against the principles of Django, which is to provide clean, simple and human-friendly URLs.

Setting up Sessions in Django

Although this should already be setup and working correctly, it's nevertheless good practice to learn which Django modules provide which functionality. In the case of sessions, Django provides middleware¹⁵² that implements session functionality.

¹⁵¹http://en.wikipedia.org/wiki/Session_(computer_science)

¹⁵² https://docs.djangoproject.com/en/2.0/topics/http/middleware/

To check that everything is in order, open your Django project's settings.py file. Within the file, locate the MIDDLEWARE list. You should find within this list a module represented by the string django.contrib.sessions.middleware.SessionMiddleware.If you can't see it, add it to the list now. It is the SessionMiddleware middleware that enables the creation of unique sessionid cookies.

The SessionMiddleware is designed to work flexibly with different ways to store session information. There are many approaches that can be taken - you could store everything in a file, in a database, or even in a in-memory cache. The most straightforward approach is to use the django.contrib.sessions application to store session information in a Django model/database (specifically, the model django.contrib.sessions.models.Session). To use this approach, you'll also need to make sure that django.contrib.sessions is in the INSTALLED_APPS tuple of your Django project's settings.py file. Remember, if you add the application now, you'll need to update your database with the usual migration commands.

Caching Sessions

If you want faster performance, you may want to consider a cached approach for storing session information. You can check out the Django documentation for advice on cached sessions¹⁵³.

A Cookie Tasting Session

While all modern Web browsers support cookies, certain cookies may get blocked depending on your browser's security level. Check that you've enabled support for cookies before continuing. It's likely however that everything is ready for you to proceed.

Testing Cookie Functionality

To test out cookies, you can make use of some convenience methods provided by Django's request object. The three of particular interest to us are set_test_cookie(), test_cookie_worked() and delete_test_cookie(). In one view, you will need to set the test cookie. In another, you'll need to test that the cookie exists. Two different views are required for testing cookies because you need to wait to see if the client has accepted the cookie from the server.

We'll use two pre-existing views for this simple exercise, index() and about(). Instead of displaying anything on the pages themselves, we'll be making use of the terminal output from the Django development server to verify whether cookies are working correctly.

In Rango's views.py file, locate your index() view. Add the following line to the view. To ensure the line is executed, make sure you put it as the first line of the view.

¹⁵³https://docs.djangoproject.com/en/2.0/topics/http/sessions/#using-cached-sessions

```
request.session.set_test_cookie()
```

In the about() view, add the following three lines to the top of the function.

```
if request.session.test_cookie_worked():
    print("TEST COOKIE WORKED!")
    request.session.delete_test_cookie()
```

With these small changes saved, run the Django development server and navigate to Rango's homepage, http://127.0.0.1:8000/rango/. Now navigate to the about page, you should see TEST COOKIE WORKED! appear in your Django development server's console, like in the figure below.

A screenshot of the Django development server's console output with the TEST COOKIE WORKED! message.

If the message isn't displayed, you'll want to check your browser's security settings. The settings may be preventing the browser from accepting the cookie.

Client Side Cookies: A Site Counter Example

Now we know how cookies work, let's implement a very simple site visit counter. To achieve this, we're going to be creating two cookies: one to track the number of times the user has visited the Rango app, and the other to track the last time they accessed the site. Keeping track of the date and time of the last access will allow us to only increment the site counter once per day (for example) and thus avoid people spamming the site to increment the counter.

The sensible place to assume where a user enters the Rango site is at the index page. Open Rango's view.py file. Let's first make a function – given a handle to both the request and response objects – to handle cookies (visitor_cookie_handler()). We can then make use of this function in Rango's index() view. In views.py, add in the following function. Note that it is not technically a view, because it does not return a response object – it is just a helper function¹⁵⁴.

 $^{^{154}} https://web.cs.wpi.edu/\sim cs1101/a05/Docs/creating-helpers.html$

```
def visitor_cookie_handler(request, response):
    # Get the number of visits to the site.
    # We use the COOKIES.get() function to obtain the visits cookie.
    # If the cookie exists, the value returned is casted to an integer.
    # If the cookie doesn't exist, then the default value of 1 is used.
   visits = int(request.COOKIES.get('visits', '1'))
    last_visit_cookie = request.COOKIES.get('last_visit', str(datetime.now()))
    last_visit_time = datetime.strptime(last_visit_cookie[:-7],
                                        '%Y-%m-%d %H:%M:%S')
    # If it's been more than a day since the last visit...
    if (datetime.now() - last_visit_time).days > 0:
       visits = visits + 1
        # Update the last visit cookie now that we have updated the count
       response.set_cookie('last_visit', str(datetime.now()))
    else:
       # Set the last visit cookie
       response.set_cookie('last_visit', last_visit_cookie)
    # Update/set the visits cookie
   response.set_cookie('visits', visits)
```

This helper function takes the request and response objects – because we want to be able to access the incoming cookies from the request, and add or update cookies in the response. In the function, you can see that we call the request.COOKIES.get() function, which is a further helper function provided by Django. If the cookie exists, it returns the value. If it does not exist, we can provide a default value. Once we have the values for each cookie, we can calculate whether a day (.days) has elapsed between the last visit.

If you want to test this code out without having to wait a day, change days to seconds. That way the visit counter can be updated every second, as opposed to every day.

Note that all cookie values are returned as strings; do not assume that a cookie storing whole numbers will return an integer. You have to manually cast this to the correct type yourself because there's no place in which to store additional information within a cookie telling us of the value's type.

If a cookie does not exist, you can create a cookie with the set_cookie() method of the response object you create. The method takes in two values, the name of the cookie you wish to create (as a string), and the value of the cookie. In this case, it doesn't matter what type you pass as the value it will be automatically cast to a string.

Since we are using the datetime we need to import this into views.py at the top of the file.

```
from datetime import datetime
```

Next, update the index() view to call the cookie_handler_function() helper function. To do this, we need to extract the response first.

```
def index(request):
    category_list = Category.objects.order_by('-likes')[:5]
    page_list = Page.objects.order_by('-views')[:5]
    context_dict = {'categories': category_list, 'pages': page_list}

# Obtain our Response object early so we can add cookie information.
    response = render(request, 'rango/index.html', context_dict)

# Call the helper function to handle the cookies
    visitor_cookie_handler(request, response)

# Return response back to the user, updating any cookies that need changed.
    return response
```

A screenshot of Google Chrome with the Developer Tools open showing the cookies for Rango, using the Django development server at 127.0.0.1. Note the visits cookie - the user has visited a total of three times, with each visit at least one day apart.

Now if you visit the Rango homepage and open the cookie inspector provided by your browser (e.g. Google Chrome's Developer Tools), you should be able to see the cookies visits and last_visit. The figure above demonstrates the cookies in action. Instead of using the developer tools, you could update the index.html and add visits: {{ visits }} to the template to show the number of visits, and updating the context dictionary to include the visits value (i.e. 'visits': int(request.COOKIES.get('visits', '1')),).

Session Data

The previous example shows how we can store and manipulate client side cookies - or the data stored on the client. However, a more secure way to save session information is to store any such data on the server side. We can then use the session ID cookie that is stored on the client side (but is effectively anonymous) as the key to access the data.

To use session-based cookies you need to perform the following steps.

1. Make sure that the MIDDLEWARE_CLASSES list found in the settings.py module contains django.contrib.sessions.middleware.SessionMiddleware.

2. Configure your session backend. Make sure that django.contrib.sessions is in your INSTALLED_-APPS in settings.py. If not, add it, and run the database migration command, python manage.py migrate.

3. By default a database backend is assumed, but you might want to a different setup (i.e. a cache). See the Django documentation on sessions for other backend configurations¹⁵⁵.

Instead of storing the cookies directly in the request (and thus on the client's machine), you can access server-side data via the method request.session.get() and store them with request.session[]. Note that a session ID cookie is still used to remember the client's machine (so technically a browser side cookie exists). However, all the user/session data is stored server side. Django's session middleware handles the client side cookie and the storing of the user/session data.

To use the server side data, we need to refactor the code we have written so far. First, we need to update the visitor_cookie_handler() function so that it accesses the cookies on the server side. We can do this by calling request.session.get(), and store them by placing them in the dictionary request.session[]. To help us along, we have made a helper function called get_server_side_cookie() that asks the request for a cookie. If the cookie is in the session data, then its value is returned. Otherwise, the default value is returned.

Since all the cookies are stored server side, we won't be changing the response directly. Because of this, we can remove response from the visitor_cookie_handler() function definition.

```
# A helper method
def get_server_side_cookie(request, cookie, default_val=None):
   val = request.session.get(cookie)
    if not val:
       val = default_val
   return val
# Updated the function definition
def visitor_cookie_handler(request):
   visits = int(get_server_side_cookie(request, 'visits', '1'))
    last_visit_cookie = get_server_side_cookie(request,
                                                'last_visit',
                                               str(datetime.now()))
    last_visit_time = datetime.strptime(last_visit_cookie[:-7],
                                        '%Y-%m-%d %H:%M:%S')
    # If it's been more than a day since the last visit...
    if (datetime.now() - last_visit_time).days > 0:
        visits = visits + 1
        #update the last visit cookie now that we have updated the count
```

¹⁵⁵https://docs.djangoproject.com/en/2.0/topics/http/sessions/

```
request.session['last_visit'] = str(datetime.now())
else:
    # set the last visit cookie
    request.session['last_visit'] = last_visit_cookie

# Update/set the visits cookie
request.session['visits'] = visits
```

Now that we have updated the handler function, we can now update the index() view. First change visitor_cookie_handler(request, response) to visitor_cookie_handler(request). Then add in the following line to pass the number of visits to the context dictionary.

```
context_dict['visits'] = request.session['visits']
```

Make sure that these lines are executed before render() is called, or your changes won't be executed. The index() view should look like the code below. Notice that the order in which the methods are called is different because we no longer need manipulate the cookies in the response.

```
def index(request):
    request.session.set_test_cookie()
    category_list = Category.objects.order_by('-likes')[:5]
    page_list = Page.objects.order_by('-views')[:5]
    context_dict = {'categories': category_list, 'pages': page_list}

    visitor_cookie_handler(request)
    context_dict['visits'] = request.session['visits']

    response = render(request, 'rango/index.html', context=context_dict)
    return response
```

Before you restart the Django development server, delete the existing client side cookies to start afresh. See the warning below for more information.

Avoiding Cookie Confusion

It's highly recommended that you delete any client-side cookies for Rango *before* you start using session-based data. You can do this in your browser's cookie inspector by deleting each cookie individually, or simply clear your browser's cache entirely – ensuring that cookies are deleted in the process.

Data Types and Cookies

An added advantage of storing session data server-side is its ability to cast data from strings to the desired type. This only works however for built-in types¹⁵⁶, such as int, float, long, complex and boolean. If you wish to store a dictionary or other complex type, don't expect this to work. In this scenario, you might want to consider pickling your objects¹⁵⁷.

Browser-Length and Persistent Sessions

When using cookies you can use Django's session framework to set cookies as either *browser-length* sessions or *persistent sessions*. As the names of the two types suggest:

- browser-length sessions expire when the user closes his or her browser; and
- persistent sessions can last over several browser instances expiring at a time of your choice. This could be half an hour, or even as far as a month in the future.

By default, browser-length sessions are disabled. You can enable them by modifying your Django project's settings.py module. Add the variable SESSION_EXPIRE_AT_BROWSER_CLOSE, setting it to True.

Alternatively, persistent sessions are enabled by default, with SESSION_EXPIRE_AT_BROWSER_CLOSE either set to False, or not being present in your project's settings.py file. Persistent sessions have an additional setting, SESSION_COOKIE_AGE, which allows you to specify how long the cookie can live for. This value should be an integer, representing the number of seconds the cookie can live for. For example, specifying a value of 1209600 will mean your website's cookies expire after a two week (14 day) period.

Check out the available settings you can use on the official Django documentation on cookies¹⁵⁸ for more details. You can also check out Eli Bendersky's blog¹⁵⁹ for an excellent tutorial on cookies and Django.

Clearing the Sessions Database

Sessions accumulate easily, and the data store that contains session information does too. If you are using the database backend for Django sessions, you will have to periodically clear the database that stores the cookies. This can be done using \$ python manage.py clearsessions. The Django documentation¹⁶⁰ suggests running this daily as a Cron job¹⁶¹. If you don't, you could find your app's performance begin to degrade when it begins to experience more and more users.

Basic Considerations and Workflow

When using cookies within your Django application, there are a few things you should consider.

• First, consider what type of cookies your Web application requires. Does the information you wish to store need to persist over a series of user browser sessions, or can it be safely disregarded upon the end of one session?

- Think carefully about the information you wish to store using cookies. Remember, storing
 information in cookies by their definition means that the information will be stored on
 client's computers, too. This is a potentially huge security risk: you simply don't know
 how compromised a user's computer will be. Consider server-side alternatives if potentially
 sensitive information is involved.
- As a follow-up to the previous bullet point, remember that users may set their browser's security settings to a high level that could potentially block your cookies. As your cookies could be blocked, your site may function incorrectly. You *must* cater for this scenario *you have no control over the client browser's setup*.

If client-side cookies are the right approach for you, then work through the following steps.

- 1. You must first perform a check to see if the cookie you want exists. Checking the request parameter parameter will allow you to do this. The request.COOKIES.has_key('<cookie_name>') function returns a boolean value indicating whether a cookie <cookie_name> exists on the client's computer or not.
- 2. If the cookie exists, you can then retrieve its value again via the request parameter with request .COOKIES[]. The COOKIES attribute is exposed as a dictionary, so pass the name of the cookie you wish to retrieve as a string between the square brackets. Remember, cookies are all returned as strings, regardless of what they contain. You must therefore be prepared to cast to the correct type (with int() or float(), for example).
- 3. If the cookie doesn't exist, or you wish to update the cookie, pass the value you wish to save to the response you generate. response.set_cookie('<cookie_name>', value) is the function you call, where two parameters are supplied: the name of the cookie, and the value you wish to set it to.

If you need more secure cookies, then use session based cookies.

- 1. Firstly, ensure that the MIDDLEWARE_CLASSES list in your Django project's settings.py module contains django.contrib.sessions.middleware.SessionMiddleware.If it doesn't, add it to the list.
- 2. Configure your session backend SESSION_ENGINE. See the Django Documentation on Sessions¹⁶² for the various backend configurations.

¹⁶² https://docs.djangoproject.com/en/2.0/topics/http/sessions/

- 3. Check to see if the cookie exists via requests.sessions.get().
- 4. Update or set the cookie via the session dictionary, requests.session['<cookie_name>'].

Exercises

Now you've read through this chapter and tried out the code, give these exercises a go.

- Check that your cookies are server side. Clear the browser's cache and cookies, then check to make sure you can't see the last_visit and visits variables in the browser. Note you will still see the sessionid cookie. Django uses this cookie to look up the session in the database where it stores all the server side cookies about that session.
- Update the *About* page view and template telling the visitors how many times they have visited the site. Remember to call the visitor_cookie_handler() before you attempt to get the visits cookie from the request.session dictionary, otherwise if the cookie is not set it will raise an error.

User Authentication with

Django-Registration-Redux

In a previous chapter, we added in login and registration functionality by manually coding up the URLs, views and templates. However, such functionality is common to many web application so developers have created numerous add-on applications that can be included in your Django project to reduce the amount of code required to provide: login, registration, one-step and two-step authentication, change password, password recovery, etc. In this chapter, we will change our login and register so that it uses a packaged called, django-registration-redux to provide these facilities and more.

This will mean we will need to re-factor our code to remove the login and registration functionality we previously created, and then setup and configure our project to include the django-registration-redux application. This chapter also will provide you with some experience of using external applications and show you how easily they can be plugged into your Django project.

Setting up Django Registration Redux

To start we need to first install django-registration-redux version 2.2 into your environment using pip.

```
pip install -U django-registration-redux==2.2
```

Now that it is installed, we need to tell Django that we will be using this application. Open up the settings.py file, and update the INSTALLED_APPS list:

```
INSTALLED_APPS = [
   'django.contrib.admin',
   'django.contrib.auth',
   'django.contrib.contenttypes',
   'django.contrib.sessions',
   'django.contrib.messages',
   'django.contrib.staticfiles',
   'rango',
   'registration' # add in the registration package
]
```

While you are in the settings.py file you can also add the following variables that are part of the registrations package's configuration (these settings should be pretty self explanatory):

```
# If True, users can register
REGISTRATION_OPEN = True
# One-week activation window; you may, of course, use a different value.
ACCOUNT_ACTIVATION_DAYS = 7
# If True, the user will be automatically logged in.
REGISTRATION_AUTO_LOGIN = True
# The page you want users to arrive at after they successfully log in
LOGIN_REDIRECT_URL = '/rango/'
# The page users are directed to if they are not logged in,
# and are trying to access pages requiring authentication
LOGIN_URL = '/accounts/login/'
```

In tango_with_django_project/urls.py, you can now update the urlpatterns so that it includes a reference to the registration package:

```
path('accounts/', include('registration.backends.simple.urls')),
```

The django-registration-redux package provides a number of different registration backends, depending on your needs. For example you may want a two-step process, where user is sent a confirmation email, and a verification link. Here we will be using the simple one-step registration process, where a user sets up their account by entering in a username, email, and password, and is automatically logged in.

Functionality and URL mapping

The Django Registration Redux package provides the machinery for numerous functions. In the registration.backend.simple.urls, it provides the following mappings:

- registration -> /accounts/register/
- registration complete -> /accounts/register/complete/
- login -> /accounts/login/
- logout -> /accounts/logout/
- password change -> /password/change/
- password reset -> /password/reset/

while in the registration.backends.default.urls it also provides the functions for activating the account in a two stage process:

- activation complete (used in the two-step registration) -> activate/complete/
- activate (used if the account action fails) -> activate/<activation_key>/
- activation email (notifies the user an activation email has been sent out)

- activation email body (a text file, that contains the activation email text)
- activation email subject (a text file, that contains the subject line of the activation email)

Now the catch. While Django Registration Redux provides all this functionality, it does not provide the templates because these tend to be application specific. So we need to create the templates associated with each view.

Setting up the Templates

In the Django Registration Redux Quick Start Guide¹⁶³, it provides an overview of what templates are required, but it is not immediately clear what goes within each template. Rather than try and work it out from the code, we can take a look at a set of templates written by Anders Hofstee¹⁶⁴ to quickly get the gist of what we need to code up.

First, create a new directory in the templates directory, called registration. This is where we will house all the pages associated with the Django Registration Redux application, as it will look in this directory for the templates it requires.

Login Template

In templates/registration create the file, login.html with the following code:

Notice that whenever a URL is referenced, the url template tag is used to reference it. If you visit, http://127.0.0.1:8000/accounts/ then you will see the list of URL mappings, and the names associated with each URL (assuming that DEBUG=True in settings.py).

¹⁶³https://django-registration-redux.readthedocs.org/en/latest/quickstart.html

¹⁶⁴https://github.com/macdhuibh/django-registration-templates

Registration Template

In templates/registration create the file, registration_form.html with the following code:

Registration Complete Template

In templates/registration create the file, registration_complete.html with the following code:

Logout Template

In templates/registration create the file, logout.html with the following code:

Try out the Registration Process

First, run python manage.py migrate to apply the database updates for the Django Registration Redux package. Then, run the server and visit: http://127.0.0.1:8000/accounts/register/.

Note how the registration form contains two fields for password - so that it can be checked. Try registering, but enter different passwords.

While this works, not everything is hooked up.

Refactoring your project

Now you will need to update the base.html so that the new registration URLs and views are used.

- Update register to point to .
- Update login to point to .
- Update logout to point to .
- In settings.py, update LOGIN_URL to be '/accounts/login/'.

Notice that for the logout, we have included a <code>?next=/rango/</code>. This is so when the user logs out, it will redirect them to the index page of Rango. If we exclude it, then they will be directed to the log out page (but that would not be very nice).

Next, decommission the register, login, logout functionality from the rango application, i.e. remove the URLs, views, and templates (or comment them out).

Modifying the Registration Flow

At the moment, when users register, it takes them to the registration complete page. This feels a bit clunky; so instead, we can take them to the main index page. Overriding the RegistrationView provided by registration.backends.simple.views can do this. Update the tango_with_django_project/urls.py by importing RegistrationView, add in the following registration class.

```
from registration.backends.simple.views import RegistrationView
from django.urls import reverse

# Create a new class that redirects the user to the index page,
#if successful at logging
class MyRegistrationView(RegistrationView):
    def get_success_url(self, user):
        return reverse('index')
```

Then update the urlpatterns list in your Django project's urls.py module by adding the following line before the pattern for accounts. Note that this is *not* the urls.py module within the rango directory!

This will allow for accounts/register to be matched before any other accounts/ URL. This allows us to redirect accounts/register to our customised registration view.

Exercise and Hints

- Provide users with password change functionality.
- Hint: see Anders Hofstee's Templates¹⁶⁵ to get started.
- Hint: the URL to change passwords is accounts/password/change/ and the URL to denote the password has been changed is: accounts/password/change/done/

 $[\]overline{\ ^{165} https://github.com/macdhuibh/django-registration-templates/tree/master/registration}$

In this chapter, we will be styling Rango using the Twitter Bootstrap 4 toolkit. Bootstrap is the most popular HTML, CSS, JS Framework, which we can use to style our application. The toolkit lets you design and style responsive web applications, and is pretty easy to use once you get familiar with it.

Cascading Style Sheets

If you are not familiar with CSS, have a look at the CSS crash course. We provide a quick guide on the basic of Cascading Style Sheets.

Now take a look at the Bootstrap 4.0 website 166 - it provides you with sample code and examples of the different components and how to style them by added in the appropriate style tags, etc. On the Bootstrap website they provide a number of example layouts¹⁶⁷ which we can base our design on.

To style Rango we have identified that the dashboard style 168 more or less meets our needs in terms of the layout of Rango, i.e. it has a menu bar at the top, a side bar (which we will use to show categories) and a main content pane.

Download and save the HTML source for the Dashboard layout to a file called, bootstrap-base.html and save it to your templates/rango directory.

Before we can use the template, we need to modify the HTML so that we can use it in our application. The changes that we performed are listed below along with the updated HTML (so that you don't have to go to the trouble and a copy of the HTML is in our [github repository] (https://raw.githubusercontent.com/leifos/tango_with_django_2/master/code/tango_with_django_project/templates/rango/bootstrap-base.html).

- Replaced all references of to be http://getbootstrap.com/docs/4.2/ as we are using version 4.2.
- Replaced dashboard.css with the absolute reference:
 - http://getbootstrap.com/docs/4.2/examples/dashboard/dashboard.css
- Removed the search form from the top navigation bar.
- Stripped out all the non-essential content from the HTML and replaced it with: - {% block body_block %}{% endblock %}
 • Set the title element to be:
- <title> Rango {% block title %}How to Tango with Django!{% endblock %} </title> Changed project name to be Rango.
- Added the links to the index page, login, register, etc to the top nav bar.
- Added in a side block, i.e., {% block side_block %}{% endblock %}
- Added in {% load staticfiles %} and {% load rango_template_tags %} after the DOCTYPE tag.

¹⁶⁸http://getbootstrap.com/examples/dashboard/

Template

Copying and Pasting

In the introductory chapter, we said not the copy and paste - but this is an exception. However, if you directly cut and paste you will end up bringing additional text you do not want. So go to our github page and get the [base template] (https://raw.githubusercontent.com/leifos/tango_with_django_2/master/code/tango_with_django_project/templates/rango/bootstrap-base.html) shown below.

Also, If you don't understand what the specific Bootstrap classes do, then you can check out the Bootstrap Documentation¹⁶⁹.

```
<!DOCTYPE html>
{% load staticfiles %}
{% load rango_template_tags %}
<html lang="en">
  <head>
    <meta charset="utf-8">
    <meta name="viewport" content="width=device-width, initial-scale=1, shrink-to-fi\</pre>
t=no">
    <meta name="description" content="">
    <meta name="author" content="Mark Otto, Jacob Thornton, and Bootstrap contributo\</pre>

        </body>
</html>
```

Once you have the new template setup, you can download the Rango Favicon¹⁷⁰ and save it to static/images/.

If you take a close look at the modified Dashboard HTML source, you'll notice it has a lot of structure in it created by a series of <div> tags. Essentially the page is broken into two parts - the top navigation

 $^{^{170}} https://raw.githubusercontent.com/leifos/tango_with_django_2/master/code/tango_with_django_project/static/images/favicon.ico.$

bar which is contained by header> tags, and the main content pane denoted by the <main ... > tag.
Within the main content pane, there is a <div> which houses two other divs for the sidebar_block
and the body block.

The code above assumes that you have completed the chapters on User Authentication and used the Django Regisration Redux Package. If not you will need to update the template and remove/modify the references to those links in the navigation bar in the header.

Also of note is that the HTML template makes references to external websites to request the required css and js files. So you will need to be connected to the internet for the style to be loaded when you run the application.

Working Offline?

Rather than including external references to the css and js files, you could download all the associated files and store them in your static directory. If you do this, simply update the base template to reference the static files stored locally.

Quick Style Change

To give Rango a much needed facelift, we can replace the content of the existing base.html with the HTML template code in base_bootstrap.html. You might want to first copy out the existing code in base.html and then copy in the base_bootstrap.html code.

Now reload your application. Pretty nice! Well, sort of.

You should notice that your application looks about a hundred times better already. Below we have some screen shots of the about page showing the before and after.

Flip through the different pages. Since they all inherit from base, they will all be looking better, but not perfect! In the remainder of this chapter, we will go through a number of changes to the templates and use various Bootstrap classes to improve the look and feel of Rango.

A screenshot of the About page without styling.

A screenshot of the About page with Bootstrap Styling applied.

Sidebar Categories

For of all the sidebar categories are not displaying very nicely. If we take a look at the HTML source code for the Dashboard page¹⁷¹, we can notice that a few classes have been added to the
 tags to denote that they are nav-items and nav-links respectively. So update the template as shown below.

```
class="nav flex-column">
{% if cats %}
   {% for c in cats %}
   {% if c == act_cat %}
       class="nav-item">
             <a class="nav-link active" href="{% url 'rango:show_category' c.slug \</pre>
%}">
                               <span data-feather="archive"></span>
                               {{ c.name }}</a>
       {% else %}
       class="nav-item">
           <a class="nav-link" href="{% url 'rango:show_category' c.slug %}">
                             <span data-feather="archive"></span>{{ c.name }}</a>
       {% endif %}
{% endfor %}
{% else %}
   No Categories Yet!
{% endif %}
```

Also, rather than using <code>strong</code> to show that the category page has been selected, we have added the active class to the active category. We can also add in a feather-icon using the <code>span....</code> tag. Here we chose the archive icon, but you can see that there are loads of icons to choose from at Feather Icons (https://feathericons.com/)

The Index Page

For the index page it would be nice to show the top categories and top pages in two separate columns, while the title is at the top.

Looking at the Bootstrap examples, we can see that in the Jumbotron¹⁷² example, they have a neat header element (i.e. the jumbotron) which we can put our title message in. And so we can update the index.html as follows:

¹⁷¹https://getbootstrap.com/docs/4.2/examples/dashboard/

¹⁷² https://getbootstrap.com/docs/4.2/examples/jumbotron/

<div class="jumbotron p-4"> <div class="container"> <h1 class="jumbotron-heading">Rango says...</h1>
<div> <h2 class="h2"> Howdy {{ user.username }}! Hey there partner! </h2>

You might notice that after the jumbotron we have put p-4. The p-4 controls the spacing¹⁷³ around the jumbotron. Try changing the padding to be p-6 or p-1. You can also control the space of the top, bottom, left and right by specifically setting pt, pb, pr and p1.

</div>

Exercise

• Update all other templates so that the page heading is encapsulated within a jumbotron. This will make the whole application have a consistent look and feel.

Then to create the two columns, we draw upon the Album¹⁷⁴ example. While it has three columns, called cards, we only need two. Most, if not all, CSS frameworks use a grid layout¹⁷⁵ consisteing of 12 blocks. If you inspect the HTML souce for the Album you will see that within a row there is a <div> which sets the size of the cards <div class="col-md-4"> followed by <div class="card mb-4 shadow-sm">. This sets each card to be 4 units in length relative to the width (and 4 by 3 is 12). Since we want two cards (one for the most popular pages and most popular categories) then we can change the 4 to a 6 (i.e. 2 by 6 is 12). And so you can update the index.html with the following HTML.

¹⁷³ https://getbootstrap.com/docs/4.2/utilities/spacing/

¹⁷⁴https://getbootstrap.com/docs/4.2/examples/album/

¹⁷⁵https://getbootstrap.com/docs/4.2/layout/grid/

```
{% endfor %}
                {% else %}
                <strong>There are no categories present.
                {% endif %}
       </div>
</div>
</div>
<div class="col-md-6">
<div class="card mb-6">
<div class="card-body">
       <h2>Most Viewed Pages</h2>
   {% if pages %}
       <u1>
              {% for page in pages %}
               <a href="{{ page.url }}">{{ page.title }}</a>
               {% endfor %}
               {% else %}
               <strong>There are no pages present.
              {% endif %}
       </div>
</div>
</div>
</div>
</div>
```

Once you have updated the template, reload the page - it should look a lot better now, but the way the list items are presented is pretty horrible.

Let's use the list group styles provided by Bootstrap¹⁷⁶ to improve how they look. We can do this quite easily by changing the
 class="list-group"> and the elements to
 class="list-group"> and the elements to
 class="list-group"> and the elements to

¹⁷⁶https://getbootstrap.com/docs/4.2/components/list-group/

A screenshot of the Index page with a Jumbotron and Columns.

The Login Page

Now let's turn our attention to the login page. On the Bootstrap website you can see they have already made a nice login form¹⁷⁷. If you take a look at the source, you'll notice that there are a number of classes that we need to include to stylise the basic login form. Update the body_block in the login.html template as follows:

```
{% block body_block %}
<link href="https://getbootstrap.com/docs/4.0/examples/signin/signin.css"</pre>
    rel="stylesheet">
<div class="jumbotron p-4">
    <h1 class="jumbotron-heading">Login</h1>
</div>
<div class="container">
<form class="form-signin" role="form" method="post" action=".">
    {% csrf_token %}
    <h2 class="form-signin-heading">Please sign in</h2>
    <label for="inputUsername" class="sr-only">Username</label>
    <input type="text" name="username" id="id_username" class="form-control"</pre>
           placeholder="Username" required autofocus>
    <label for="inputPassword" class="sr-only">Password</label>
    <input type="password" name="password" id="id_password" class="form-control"</pre>
           placeholder="Password" required>
    <button class="btn btn-lg btn-primary btn-block" type="submit"</pre>
            value="Submit" />Sign in</button>
</form>
</div>
{% endblock %}
```

Besides adding in a link to the bootstrap signin.css, and a series of changes to the classes associated with elements, we have removed the code that automatically generates the login form, i.e. form.as_p. Instead, we took the elements, and importantly the id of the elements generated and associated them with the elements in this bootstrapped form. To find out what these ids were, we ran Rango, navigated to the page, and then inspected the source to see what HTML was produced by the form.as_p template tag.

 $^{^{177}} https://getbootstrap.com/docs/4.2/examples/signin/\\$

In the button, we have set the class to btn and btn-primary. If you check out the Bootstrap section on buttons¹⁷⁸ you can see there are lots of different colours, sizes and styles that can be assigned to buttons.

A screenshot of the login page with customised Bootstrap Styling.

Other Form-based Templates

You can apply similar changes to add_cagegory.html and add_page.html templates. For the add_page.html template, we can set it up as follows.

```
{% extends "rango/base.html" %}
{% block title %}Add Page{% endblock %}
{% block body_block %}
        <div class="jumbotron p-4">
                 <div class="container">
                          <h1 class="jumbotron-heading">Add Page to {{category.name}}</h1>
                 </div>
        </div>
        <div class="container">
                <div class="row">
               <form role="form" id="page_form" method="post"</pre>
                      action="/rango/category/{{category.slug}}/add_page/">
               {% csrf_token %}
               {% for hidden in form.hidden_fields %}
                    {{ hidden }}
               {% endfor %}
               {% for field in form.visible_fields %}
                   {{ field.errors }}
                   {{ field.help_text }} <br/>
                    {{ field }} <br/>
                            <div class="p-2"></div>
               {% endfor %}
               <br/>
               <button class="btn btn-primary"</pre>
                        type="submit" name="submit">
                   Add Page
```

¹⁷⁸ https://getbootstrap.com/docs/4.2/components/buttons/

Exercise

• Create a similar template for the Add Category page called add_category.html.

The Registration Template

For the registration_form.html, we can update the form as follows:

```
{% extends "rango/base.html" %}
{% block body_block %}
<div class="jumbotron p-4">
        <div class="container">
                 <h1 class="jumbotron-heading">Register Here</h1>
</div>
</div>
<div class="container">
        <div class="row">
                <div class="form-group" >
            <form role="form" method="post" action=".">
                {% csrf_token %}
                <div class="form-group" >
                <label class="required" for="id_username">
                    Username:</label>
                    <input class="form-control" id="id_username" maxlength="30"</pre>
                         name="username" type="text" />
                    <span class="helptext">
                    Required. 30 characters or fewer. Letters, digits and \frac{0}{...} only.
                    </span>
```

```
<label class="required" for="id_email">
                  E-mail:</label>
                  <input class="form-control" id="id_email" name="email"</pre>
                       type="email" />
               <label class="required" for="id_password1">
                  Password: </label>
                  <input class="form-control" id="id_password1" name="password1"</pre>
                      type="password" />
               <label class="required" for="id_password2">
                      Password confirmation: </label>
                  <input class="form-control" id="id_password2" name="password2"</pre>
                       type="password" />
                  <span class="helptext">
                       Enter the same password as before, for verification.
                  </span>
               </div>
               <button type="submit" class="btn btn-primary">Submit
       </div>
</div>
</div>
{% endblock %}
```

Again we have manually transformed the form created by the {{ form.as_p }} template tag, and added the various bootstrap classes.

Bootstrap, HTML and Django Kludge

This is not the best solution - we have kind of kludged it together. It would be much nicer and cleaner if we could instruct Django when building the HTML for the form to insert the appropriate classes. But we will leave that to you to figure out :-)

Next Steps

In this chapter we have described how to quickly style your Django application using the Bootstrap toolkit. Bootstrap is highly extensible and it is relatively easy to change themes - check out the

StartBootstrap Website¹⁷⁹ for a whole series of free themes. Alternatively, you might want to use a different CSS toolkit like: Zurb¹⁸⁰, Gridism¹⁸¹, Pure¹⁸² or GroundWorkd¹⁸³. Now that you have an idea of how to hack the templates and set them up to use a responsive CSS toolkit, we can now go back and focus on finishing off the extra functionality that will really pull the application together.

A screenshot of the Registration page with customised Bootstrap Styling.

Another Style Exercise

While this tutorial uses Bootstrap, an additional, and optional exercise, would be to style Rango using one of the other responsive CSS toolkits. If you do create your own style, let us know and we can link to it to show others how you have improved Rango's styling!

¹⁷⁹http://startbootstrap.com/

¹⁸⁰http://zurb.com

¹⁸¹http://cobyism.com/gridism/

¹⁸²https://purecss.io

¹⁸³https://groundworkcss.github.io/groundwork/

Template Tags

Providing Categories on Every Page

It would be nice to show the different categories that users can browse through in the sidebar on each page. Given what we have learnt so far we could do the following:

- In the base.html template we could add some code to display an item list of categories, if the category list has been passed through.
- Then in each view, we could access the Category object, get all the categories, and return that in the context dictionary.

However, this is a pretty nasty solution. It requires a lot of cutting and pasting of code. Also, we will run into problems, when we want to show the categories on pages serviced by the django-registration-redux package. So we need a different approach, by using templatetags that are included in the template that request the data required.

Using Template Tags

Create a directory rango/templatetags, and create two files, one called __init__.py, which will be empty, and another called, rango_extras.py, where you can add the following code:

```
from django import template
from rango.models import Category

register = template.Library()

@register.inclusion_tag('rango/cats.html')
def get_category_list():
    return {'cats': Category.objects.all()}
```

As you can see we have made a method called, get_category_list() which returns the list of categories, and that is assocaited with a template called rango/cats.html. Now create a template called 'rango/cats.html' in the templates directory with the following code:

Template Tags 139

Now in yourbase.htmlyou can access the template tag by first loading it up with{% load rango_-extras %} and then slotting it into the page with{% get_category_list %}, i.e.:

Restart Server to Register Tags

You will need to restart your server every time you modify the template tags. Otherwise they will not be registered, and you will be really confused why your code is not working.

Parameterised Template Tags

Now lets extend this so that when we visit a category page, it highlights which category we are in. To do this we need to paramterise the templatetag. So update the method in rango_extras.py to be:

```
def get_category_list(cat=None):
return {'cats': Category.objects.all(), 'act_cat': cat}
```

This lets us pass through the category we are on. We can now update the base.html to pass through the category, if it exists.

Template Tags 140

Now update thecats.html template:

Here we check to see if the category being displayed is the same as the category being passed through (i.e.act_cat), if so, we assign theactive class to it from Bootstrap (http://getbootstrap.com/components/#nav). Restart the development web server, and now visit the pages. We have passed through the category variable. When you view a category page, the template has access to the category variable, and so provides a value to the template tag get_category_list(). This is then used in the cats.html template to select which category to highlight as active.

Now that our Rango application is looking good and most of the core functionality has been implemented, we can move onto some of the more advanced functionality. In this chapter, we will connect Rango up to a search API so that users can also search for pages, rather than just browse categories. The main point of this chapter is to show you how you can connect and use other web services - and how to integrate them within your own application.

The search API that we will be using will be Microsoft's Bing Search API, but you could as easily use the APIs provided by Webhose¹⁸⁴ or Yandex¹⁸⁵, instead.

To use the Bing Search API we will need to write a wrapper¹⁸⁶, which enables us to send a query and obtain the results from their API - and bring them back in a more convienent format. But, before we can do so, we first need to set up an Azure account to use Bing's Search API.

The Bing Search API

The Bing Search API¹⁸⁷ provides you with the ability to embed search results from the Bing search engine within your own applications. Through a straightforward interface, you can request results from Bing's servers to be returned in either XML or JSON. The data returned can then be interpreted by a XML or JSON parser, with the results then rendered as part of a template within your application.

Although the Bing API can handle requests for different kinds of content, we'll be focusing on web search only for this tutorial - as well as handling JSON responses. To use the Bing Search API, you will need to sign up for an *API key*. The key currently provides subscribers with access to 3000 queries per month, which should be more than enough for our purposes.

Application Programming Interface (API)

An Application Programming Interface¹⁸⁸ specifies how software components should interact with one another. In the context of web applications, an API is considered as a set of HTTP requests along with a definition of the structures of response messages that each request can return. Any meaningful service that can be offered over the Internet can have its own API - we aren't limited to web search. For more information on web APIs, Luis Rei provides an excellent tutorial on APIs¹⁸⁹.

Registering for a Bing API Key

To obtain a Bing API key, you must first register for a Microsoft Azure account. The account provides you with access to a wide range of Microsoft services. If you already have a Microsoft account, you dont need to register you can log in. Otherwise, you can go online and create a free account with Microsoft at https://account.windowsazure.com¹⁹⁰.

When your account has been created, log in and go to the portal.

On the left hand side of the page you should see a list, and at the top of the list it should say + Create a resource. Click on create a resource, and then select AI + Machine Learning. Scroll through the options, and select the Bing Search v7 option, follow the instructions and register for the service. Make sure you select the F0 Free pricing tier, which enables you to make 3000 calls per month - which is more than enough for our purposes.

The Bing Search API services - sign up for the 3,000 transactions/month for free.

Once you've signed up, and added the Bing Search v7 API, select the service, and click on the Keys tab. Here you will be able to access two keys - which you should not share with anyone.

The Account Information Page. In this screenshot, the *Primary Account Key* is deliberately obscured. You should make sure you keep your keys secret!

Assuming this all works take a copy of your API key. We will need this when we make requests as part of the authentication process.

Adding Search Functionality

Below we have provided the code that we can use to issue queries to the Bing search service. Create a file called rango/bing_search.py and import the following code. You will note that we need to import a package called requests so that we can make web requests. However, to use the requests package you will need to run, pip install requests to install it with your virtual environment, first.

¹⁹⁰https://account.windowsazure.com

```
import json
1
    import requests
 3
    # Add your Microsoft Account Key to a file called bing.key
 4
    def read_bing_key():
5
            n n n
 6
 7
            reads the BING API key from a file called 'bing.key'
            returns: a string which is either None, i.e. no key found, or with a key
8
9
            remember to put bing.key in your .gitignore file to avoid committing it to the repo.
10

33
34
    ce
            n n n
35
            bing_key = read_bing_key()
36
            search_url = 'https://api.cognitive.microsoft.com/bing/v7.0/search'
37
            headers = {"Ocp-Apim-Subscription-Key" : bing_key}
38
            params = {"q": search_terms, "textDecorations":True, "textFormat":"HTML"}
39
            response = requests.get(search_url, headers=headers, params=params)
40
41
            response.raise_for_status()
            search_results = response.json()
42
            results = []
43
```

In the module(s) above, we have implemented two functions: one to retrieve your Bing API key from a local file, and another to issue a query to the Bing search engine. Below, we discuss how both of the functions work.

read_bing_key() - Reading the Bing Key

The read_bing_key() function reads in your key from a file called bing.key, located in your Django project's root directory (i.e. workspace>/tango_with_django/). We have created this function because if you are putting your code into a public repository on GitHub for example, you should take some precautions to avoid sharing your API Key publicly.

From the Azure website, take a copy of your *Account key* and save it into <code>workspace</code>/tango_with_django/bing.key. The key should be the only contents of the file - nothing else should exist within it. This file should NOT be committed to your GitHub repository. To make sure that you do not accidentally commit it, update your repository's <code>.gitignore</code> file to exclude any files with a <code>.key</code> extension, by adding the line * <code>.key</code>. This way, your key file will only be stored locally and you will not end up with someone using your query quota (or worse).

Keys and Rings

Keep them secret, keep them safe!

run_query() - Executing the Query

The run_query() function takes a query as a string, and returns the top ten results from Bing in a list that contains a dictionary of the result items (including the title, a link, and a summary).

To summarise though, the logic of the run_query() function can be broadly split into six main tasks.

- First, the function prepares for connecting to Bing by preparing the URL that we'll be requesting.
- The function then prepares authentication, making use of your Bing API key. This is obtained by calling read_bing_key(), which in turn pulls your Account key from the bing.key file you created earlier.
- The response is then parsed into a Python dictionary object using the json Python package.

• We loop through each of the returned results, populating a results dictionary. For each result, we take the title of the page, the link or URL and a short summary of each returned result.

• The list of dictionaries is then returned by the function.

Bing it on!

There are many different parameters that the Bing Search API can handle which we don't cover here. If you want to know more about the API check out the Bing Search API Documentation¹⁹¹.

Exercises

Extend your bing_search.py module so that it can be run independently, i.e. running python bing_search.py from your terminal or Command Prompt. Specifically, you should implement functionality that:

- prompts the the user to enter a query, i.e. use raw_input(); and
- issues the query via run_query(), and prints the results.

Update the run_query() method so that it handles network errors gracefully.

Hint

Add the following code, so that when you run python bing_search.py it calls the main() function:

```
def main():
    #insert your code here

if __name__ == '__main__':
    main()
```

When you run the module explicitly via python <code>bing_search.py</code>, the <code>bing_search</code> module is treated as the <code>__main__</code> module, and thus triggers <code>main()</code>. However, when the module is imported by another module, then <code>__name__</code> will not equal <code>__main__</code>, and thus the <code>main()</code> function not be called. This way you can import it with your application without having to call <code>main()</code>.

 $^{^{191}} https://docs.microsoft.com/en-gb/rest/api/cognitiveservices/bing-web-api-v7-reference$

Putting Search into Rango

Now that we have successfully implemented the search functionality module, we need to integrate it into our Rango app. There are two main steps that we need to complete for this to work.

- We must first create a search.html template that extends from our base.html template. The search.html template will include a HTML <form> to capture the user's query as well as template code to present any results.
- We then create a view to handle the rendering of the search.html template for us, as well as calling the run_query() function we defined above.

Adding a Search Template

Let's first create a template called, rango/search.html. Add the following HTML markup, Django template code, and Bootstrap classes.

```
{% extends 'rango/base.html' %}
    {% load staticfiles %}
 3
    {% block title %} Search {% endblock %}
 4
 5
6
    {% block body_block %}
    <div>
        <h1>Search with Rango</h1>
8
        <br/>
9
        <form class="form-inline" id="user_form"</pre>
10
               method="post" action="{% url 'rango:search' %}">
11
12
             {% csrf_token %}
             <div class="form-group">
13
                 <input class="form-control" type="text" size="50"</pre>
14
                         name="query" value="" id="query" />
15
16
             <button class="btn btn-primary" type="submit" name="submit"</pre>
17
                     value="Search">Search</button>
18
        </form>
19
20
        <div>
21
             {% if result_list %}
22
             <h3>Results</h3>
23
             <!-- Display search results in an ordered list -->
24
25
             <div class="list-group">
```

```
{% for result in result_list %}
26
               <div class="list-group-item">
27
                   <h4 class="list-group-item-heading">
2.8
                       <a href="{{ result.link }}">{{ result.title|safe|escape}}</a>
29
                       </h4>
30
                       {{ result.summary|safe|escape }}\
31
32
   </div>
33
           {% endfor %}
34
           </div>
35
36
           {% endif %}
       </div>
37
38
   </div>
39
   {% endblock %}
```

The template code above performs two key tasks.

- In all scenarios, the template presents a search box and a search buttons within a HTML <form> for users to enter and submit their search queries.
- If a results_list object is passed to the template's context when being rendered, the template then iterates through the object displaying the results contained within.

To style the HTML, we have made use of Bootstrap jumbotron¹⁹², list groups¹⁹³, and forms¹⁹⁴.

To render the title and summary correctly, we have used the safe and escape tags to inform the template that the result.title and result.summary should be rendered as is (i.e. as HTML).

In the view code, in the next subsection, we will only pass through the results to the template, when the user issues a query. Initially, there will be no results to show.

Adding the View

With our search template added, we can then add the view that prompts the rendering of our template. Add the following search() view to Rango's views.py module.

¹⁹²https://getbootstrap.com/docs/4.2/components/jumbotron/

¹⁹³https://getbootstrap.com/docs/4.2/components/list-group/

¹⁹⁴https://getbootstrap.com/docs/4.2/components/forms/

```
def search(request):
    result_list = []

if request.method == 'POST':
    query = request.POST['query'].strip()
    if query:
        # Run our Bing function to get the results list!
        result_list = run_query(query)

return render(request, 'rango/search.html', {'result_list': result_list})
```

By now, the code should be pretty self explanatory to you. The only major addition is the calling of the run_query() function we defined earlier in this chapter. To call it, we are required to also import the bing_search.py module, too. Ensure that before you run the script that you add the following import statement at the top of the views.py module.

```
from rango.bing_search import run_query, read_bing_key
```

You'll also need to ensure you do the following, too.

- Add a mapping between your search() view and the /rango/search/ URL calling it name='search' by adding in path('search/', views.search, name='search'), to rango/urls.py.
- Also, update the base.html navigation bar to include a link to the search page. Remember to use the url template tag to reference the link.
- You will need a copy of the bing.key in your project's root directory (<workspace>/tango_-with_django_project, alongside manage.py).

Once you have put in the URL mapping and added a link to the search page, you should now be able issue queries to the Bing Search API and have the results shown within the Rango app (as shown in the figure below).

Searching for "Python for Noobs".

Additional Exercise

You may notice that when you issue a query, the query disappears when the results are shown. This is not very user friendly. Update the view and template so that the user's query is displayed within the search box.

Within the view, you will need to put the query into the context dictionary. Within the template, you will need to show the query text in the search box.

Making Rango Tango! Exercises

So far we have been adding in different pieces of functionality to Rango. We've been building up the application in this manner to get you familiar with the Django Framework, and to learn about how to construct the various parts of an application. However, at the moment, Rango is not very cohesive or interactive. In this chapter, we challenge you to improve the application and its user experience by bringing together some of the functionality that we have already implemented along with some other features.

To make Rango more coherent, integrated and interactive, it would be nice to add the following functionality.

- Track the clicks on Categories and Pages, i.e.:
 - count the number of times a category is viewed
 - count the number of times a page is viewed via Rango, and
 - collect likes for categories (see Django and Ajax Chapter).
- Integrate the browsing and searching within categories, i.e.:
 - instead of having a disconnected search page, let users search for pages on each specific category page, and
- let users filter the set of categories shown in the side bar (see Django and Ajax Chapter).
 Provide services for Registered Users, i.e.:
- - Assuming you have switched the django-registration-redux, we need to setup the registration form to collect the additional information (i.e. website, profile picture)
 - let users view their profile
 - let users edit their profile, and
 - let users see the list of users and their profiles.

Note

We won't be working through all of these tasks right now. Some will be taken care of in the Django and Ajax Chapter¹⁹⁵, while others will be left to you to complete as additional exercises.

Before we start to add this additional functionality we will make a todo list to plan our workflow for each task. Breaking tasks down into sub-tasks will greatly simplify the implementation so that we are attacking each one with a clear plan. In this chapter, we will provide you with the workflow for a number of the above tasks. From what you have learnt so far, you should be able to fill in the gaps and implement most of it on your own (except those requiring AJAX). In the following chapter, we have included hints, tips and code snippets elaborating on how to implement these features. Of course, if you get really stuck, you can always check out our implementation on GitHub.

^{195\}protect\char"007B\relax#chapter-ajax\protect\char"007D\relax

Track Page Clicks

Currently, Rango provides a direct link to external pages. This is not very good, because we wont know which pages people visit. So to count the number of times a page is viewed via Rango you will need to perform the following steps.

- Create a new view called goto_url(), and map it to URL /rango/goto/ and name it 'name=goto'.
- The goto_url() view will examine the HTTP GET request parameters and pull out the page_id. The HTTP GET requests will look something like /rango/goto/?page_id=1.
 - In the view, select/get the page with page_id and then increment the associated views field, and save() it.
 - Have the view redirect the user to the specified URL using Django's redirect method. Remember to include the import, from django.shortcuts import redirect
 - If no parameters are in the HTTP GET request for page_id, or the parameters do not return
 a Page object, redirect the user to Rango's homepage. Use the reverse method to get the
 URL string and then redirect.
 - See Django Shortcut Functions¹⁹⁶ for more on redirect and Django Reverse Function¹⁹⁷ for more on reverse.
- Update the category.html so that it uses /rango/goto/?page_id=XXX.
 - Remember to use the url template tag instead of using the direct URL i.e.

```
<a href="{% url 'rango:goto' %}?page_id={{page.id}}}"\>
```

GET Parameters Hint

If you're unsure of how to retrieve the page_id *querystring* from the HTTP GET request, the following code sample should help you.

```
page_id = None
if request.method == 'GET':
    if 'page_id' in request.GET:
        page_id = request.GET['page_id']
```

Always check the request method is of type GET first, then you can access the dictionary request.GET which contains values passed as part of the request. If page_id exists within the dictionary, you can pull the required value out with request.GET['page_id'].

You could also do this without using a *querystring*, but through the URL instead, i.e. /rango/goto/<page_id>/. In which case you would need to create a urlpattern that pulls out the page_id, i.e. 'goto/<int:page_id>/'.

¹⁹⁶https://docs.djangoproject.com/en/2.1/topics/http/shortcuts/

¹⁹⁷ttps://docs.djangoproject.com/en/2.1/ref/urlresolvers/#django.urls.reverse

Searching Within a Category Page

Rango aims to provide users with a helpful directory of useful web pages. At the moment, the search functionality is essentially independent of the categories. It would be nicer to have search integrated within the categories. We will assume that a user will first browse through the category of interest. If they can't find a relevant page, they can then search. If they find a page that is relevant, then they can add it to the category. Let's focus on the first problem, of putting search on the category page. To do this, perform the following steps:

- Remove the generic *Search* link from the menu bar, i.e. we are decommissioning the global search functionality.
- Take the search form and results template markup from search.html and place it into category.html.
- Update the search form so that action refers back to the category page, i.e.:

```
<form class="form-inline" id="user_form"

method="post" action="{% url 'rango:show_category' category.slug %}">
```

- Update the category view to handle a HTTP POST request. The view must then include any search results in the context dictionary for the template to render.
- Also, lets make it so that only authenticated users can search. So to restrict access within the category.html template use:

```
{% if user.authenticated %}
    <!-- Insert search code here -->
{% endif %}
```

Create and View Profiles

If you have swapped over to the django-registration-redux package, then you'll have to collect the UserProfile data. To do this, instead of redirecting the user to the Rango index page, you will need to redirect them to a new form, to collect the user's profile picture and URL details. To add the UserProfile registration functionality, you need to:

- create a profile_registration.html which will display the UserProfileForm;
- create a UserProfileForm ModelForm class to handle the new form;
- create a register_profile() view to capture the profile details;

- map the view to a URL, i.e. rango/register_profile/; and
- in the MyRegistrationView, update the get_success_url() to point to rango/add_profile/.

Another useful feature is to let users inspect and edit their own profile. Undertake the following steps to add this functionality.

- First, create a template called profile.html. In this template, add in the fields associated with the user profile and the user (i.e. username, email, website and picture).
- Create a view called profile(). This view will obtain the data required to render the user profile template.
- Map the URL /rango/profile/ to your new profile() view.
- In the base template add a link called *Profile* into the menu bar, preferably with other user-related links. This should only be available to users who are logged in (i.e. {% if user.is_authenticated %}).

To let users browse through user profiles, you can also create a users page that lists all the users. If you click on a user page, then you can see their profile. However, you must make sure that a user is only able to edit their profile!

Referencing Uploaded Content in Templates

If you have successfully completed all of the Templates and Media chapter, your Django setup should be ready to deal with the uploading and serving of user media files. You should be able to reference the MEDIA_URL URL (defined in settings.py) in your templates through use of the {{ MEDIA_URL }} tag, provided by the media template context processor¹⁹⁸, e.g. .

In the next chapter, we provide a series of hints and tips to help you complete these features.

 $^{^{198}} https://docs.djangoproject.com/en/2.1/howto/static-files/$

Hopefully, you will have been able to complete the exercises given the workflows we provided. If not, or if you need a little help, have a look at the potential solutions we have provided below, and use them within your version of Rango.

Got a better solution?

The solutions provided in this chapter are only one way to solve each problem. They are based on what we have learnt so far. However, if you implement them differently, feel free to share your solutions with us - and tweet links to @tangowithdjango for others to see.

Track Page Clickthroughs

Currently, Rango provides a direct link to external pages. This is not very good if you want to track the number of times each page is clicked and viewed. To count the number of times a page is viewed via Rango, you'll need to perform the following steps.

Creating a URL Tracking View

Create a new view called goto_url() in /rango/views.py which takes a parameterised HTTP GET request (i.e. rango/goto/?page_id=1) and updates the number of views for the page. The view should then redirect to the actual URL.

```
from django.shortcuts import redirect

def goto_url(request):
    page_id = None
    url = '/rango/'
    if request.method == 'GET':
        if 'page_id' in request.GET:
            page_id = request.GET['page_id']

        try:
            page = Page.objects.get(id=page_id)
            page.views = page.views + 1
            page.save()
```

154

```
url = page.url
except:
    pass
return redirect(url)
```

Be sure that you import the redirect() function to views.py if it isn't included already!

```
from django.shortcuts import redirect
```

Mapping URL

In /rango/urls.py add the following code to the urlpatterns tuple.

```
path('goto/', views.goto_url, name='goto'),
```

Updating the Category Template

Update the category.html template so that it uses rango/goto/?page_id=XXX instead of providing the direct URL for users to click.

Here you can see that in the template we have added some control statements to display view, views or nothing depending on the value of page.views.

Updating Category View

Since we are tracking the number of clickthroughs you can now update the category() view, and have it order the pages by the number of views:

```
pages = Page.objects.filter(category=category).order_by('-views')
```

Now, confirm it all works, by clicking on links, and then going back to the category page. Don't forget to refresh or click to another category to see the updated page.

Searching Within a Category Page

Rango aims to provide users with a helpful directory of page links. At the moment, the search functionality is essentially independent of the categories. It would be nicer however to have search integrated into category browsing. Let's assume that a user will first browse their category of interest first. If they can't find the page that they want, they can then search for it. If they find a page that is suitable, then they can add it to the category that they are in. Let's tackle the first part of this description here.

We first need to remove the global search functionality and only let users search within a category. This will mean that we essentially decommission the current search page and search view. After this, we'll need to perform the following.

Decommissioning Generic Search

Remove the generic *Search* link from the menu bar by editing the base.html template. You can also remove or comment out the URL mapping in rango/urls.py.

Creating a Search Form Template

Now in category.html, after the categories, add in a new div at the bottom of the template, and copy in the search form. This is very similar to the template code in the search.html, but we have updated the action to point to the show_category page. We also pass through a variable called query, so that the user can see what query has been issued.

After the search form, we need to provide a space where the results are rendered. Again, this code is similar to the template code in search.html.

Remember to wrap the search form and search results with {% if user.is_authenticated %} and {% endif %}, so that only authenticated users can search. You don't want random users to be wasting your monthly search API's quota! And remember to encase the search box and results in a div containter and div row <div class="container p-4"><div class="row"> ... </div></div>.

Updating the Category View

Update the category view to handle a HTTP POST request (i.e. when the user submits a search) and inject the results list into the context. The following code demonstrates this new functionality.

```
def show_category(request, category_name_slug):
    # Create a context dictionary that we can pass
    # to the template rendering engine.
    context_dict = {}
    trv:
       # Can we find a category name slug with the given name?
        # If we can't, the .get() method raises a DoesNotExist exception.
        # So the .get() method returns one model instance or raises an exception.
       category = Category.objects.get(slug=category_name_slug)
        # Retrieve all of the associated pages.
        # Note that filter() returns a list of page objects or an empty list
       pages = Page.objects.filter(category=category)
        # Adds our results list to the template context under name pages.
       context_dict['pages'] = pages
        # We also add the category object from
        # the database to the context dictionary.
```

```
# We'll use this in the template to verify that the category exists.
    context_dict['category'] = category
    # We get here if we didn't find the specified category.
    # Don't do anything -
    # the template will display the "no category" message for us.
except Category DoesNotExist:
    context_dict['category'] = None
    context_dict['pages'] = None
# New code added here to handle a POST request
# create a default query based on the category name
# to be shown in the search box
context_dict['query'] = category.name
result_list = []
if request.method == 'POST':
    query = request.POST['query'].strip()
    if query:
        # Run our search API function to get the results list!
        result_list = run_query(query)
        context_dict['query'] = query
        context_dict['result_list'] = result_list
# Go render the response and return it to the client.
return render(request, 'rango/category.html', context_dict)
```

Notice that the context_dict now includes the result_list and query. If there is no query, we provide a default query, i.e. the category name. The query box then displays this value.

Rango's updated category view, complete with search API search functionality.

Creating a UserProfile Instance

This section provides a solution for creating Rango UserProfile accounts. Recall that the standard Django auth User object contains a variety of standard information regarding an individual user, such as a username and password. We however chose to implement an additional UserProfile

model to store additional information such as a user's Website and a profile picture. Here, we'll go through how you can implement this, using the following steps.

- Create a profile_registration.html that will display the UserProfileForm.
- Create a UserProfileForm ModelForm class to handle the new form.
- Create a register_profile() view to capture the profile details.
- Map the view to a URL, i.e. rango/register_profile/.
- In the MyRegistrationView defined in the Django registration-redux chapter, update the get_success_url() to point to rango/add_profile/.

The basic flow for a registering user here would be:

- clicking the Register link;
- filling out the initial Django registration-redux form (and thus registering);
- filling out the new UserProfileForm form; and
- completing the registration.

This assumes that a user will be registered with Rango before the profile form is saved.

Creating a Profile Registration Template

First, let's create a template that'll provide the necessary markup for displaying an additional registration form. In this solution, we're going to keep the Djangoregistration-redux form separate from our Profile Registration form - just to delineate between the two.

Create a template in Rango's templates directory called profile_registration.html. Within this new template, add the following markup and Django template code.

Much like the previous Django registration-redux form that we created previously, this template inherits from our base.html template, which incorporates the basic layout for our Rango app. We also create an HTML form inside the body_block block. This will be populated with fields from a form object that we'll be passing into the template from the corresponding view (see below).

Don't Forget multipart/form-data!

When creating your form, don't forget to include the enctype="multipart/form-data" attribute in the <form> tag. We need to set this to instruct the Web browser and server that no character encoding should be used¹⁹⁹ - as we are performing *file uploads*. If you don't include this attribute, the image upload component will not work.

Creating the UserProfileForm Class

Looking at Rango's models.py module, you should see a UserProfile model that you implemented previously. We've included it below to remind you of what it contains - a reference to a Django django.contrib.auth.User object, and fields for storing a Website and profile image.

```
class UserProfile(models.Model):
    # This line is required. Links UserProfile to a User model instance.
    user = models.OneToOneField(User)
    # The additional attributes we wish to include.
    website = models.URLField(blank=True)
    picture = models.ImageField(upload_to='profile_images', blank=True)

# Override the __unicode__() method to return out something meaningful!
    def __str__(self):
        return self.user.username
```

In order to provide the necessary HTML markup on the fly for this model, we need to implement a Django ModelForm class, based upon our UserProfile model. Looking back to the chapter detailing Django forms, we can implement a ModelForm for our UserProfile as shown in the example below. Perhaps unsurprisingly, we call this new class UserProfileForm.

 $^{^{199}} http://stackoverflow.com/questions/4526273/what-does-enctype-multipart-form-data-mean \\$

```
class UserProfileForm(forms.ModelForm):
    website = forms.URLField(required=False)
    picture = forms.ImageField(required=False)

class Meta:
    model = UserProfile
    exclude = ('user',)
```

Note the inclusion of optional (through required=False) website and picture HTML form fields - and the nested Meta class that associates the UserProfileForm with the UserProfile model. The exclude attribute instructs the Django form machinery to *not* produce a form field for the user model attribute. As the newly registered user doesn't have reference to their User object, we'll have to manually associate this with their new UserProfile instance when we create it later.

Creating a Profile Registration View

Next, we need to create the corresponding view to handle the processing of a UserProfileForm form, the subsequent creation of a new UserProfile instance, and instructing Django to render any response with our new profile_registration.html template. By now, this should be pretty straightforward to implement. Handling a form means being able to handle a request to render the form (via a HTTP GET), and being able to process any entered information (via a HTTP POST). A possible implementation for this view is shown below.

```
@login_required
def register_profile(request):
    form = UserProfileForm()

if request.method == 'POST':
    form = UserProfileForm(request.POST, request.FILES)
    if form.is_valid():
        user_profile = form.save(commit=False)
        user_profile.user = request.user
        user_profile.save()

        return redirect('index')
    else:
        print(form.errors)

context_dict = {'form':form}

return render(request, 'rango/profile_registration.html', context_dict)
```

Upon creating a new UserProfileForm instance, we then check our request object to determine if a GET or POST was made. If the request was a POST, we then recreate the UserProfileForm, using data gathered from the POST request. As we are also handling a file image upload (for the user's profile image), we also need to pull the uploaded file from request.FILES. We then check if the submitted form was valid - meaning that form fields were filled out correctly. In this case, we only really need to check if the URL supplied is valid - since the URL and profile picture fields are marked as optional.

With a valid UserProfileForm, we can then create a new instance of the UserProfile model with the line user_profile = form.save(commit=False). Setting commit=False gives us time to manipulate the UserProfile instance before we commit it to the database. This is where can then add in the necessary step to associate the new UserProfile instance with the newly created User object that has been just created (refer to the flow at the top of this section to refresh your memory). After successfully saving the new UserProfile instance, we then redirect the newly created user to Rango's index view, using the URL pattern name. If form validation failed for any reason, errors are simply printed to the console. You will probably in your own code want to make the handling of errors more robust.

If the request sent was a HTTP GET, the user simply wants to request a blank form to fill out - so we respond by rendering the profile_registration.html template created above with a blank instance of the UserProfileForm, passed to the rendering context dictionary as form - thus satisfying the requirement we created in our template. This solution should therefore handle all required scenarios for creating, parsing and saving data from a UserProfileForm form.

Can't find login_required?

Remember, once a newly registered user hits this view, they will have had a new account created for them - so we can safely assume that he or she is now logged into Rango. This is why we are using the @login_required decorator at the top of our view to prevent individuals from accessing the view when they are unauthorised to do so.

If you are receiving an error stating that the <code>login_required()</code> function (used as a decorator to our new view) cannot be located, ensure that you have the following <code>import</code> statement at the top of your <code>view.py</code> module.

from django.contrib.auth.decorators import login_required

See the Django Documentation for more details about Authentication²⁰⁰.

Mapping the View to a URL

Now that our template ModelForm and corresponding view have all been implemented, a seasoned Djangoer should now be thinking: *map it!* We need to map our new view to a URL, so that users can access the newly created content. Opening up Rango's urls.py module and adding the following line to the urlpatterns list will achieve this.

 $^{^{200}} https://docs.djangoproject.com/en/2.1/topics/auth/default/$

```
path('register_profile/', views.register_profile, name='register_profile'),
```

This maps our new register_profile() view to the URL /rango/register_profile/. Remember, the /rango/ part of the URL comes from your project's urls.py module - the remainder of the URL is then handled by the Rango app's urls.py module.

Modifying the Registration Flow

Now that everything is (almost) working, we need to tweak the process that users undertake when registering. Back in the Django registration-redux chapter, we created a new class-based view called MyRegistrationView that changes the URL that users are redirected to upon a successful registration. This needs to be changes from redirecting a user to the Rango homepage (with URL name index) to our new user profile registration URL. From the previous section, we gave this the name register_profile. This means changing the MyRegistrationView class in tango_with_dango_project/urls.py to look be:

```
class MyRegistrationView(RegistrationView):
    def get_success_url(self, user):
        return reverse('rango:register_profile')
```

Now when a user registers, they should be then redirected to the profile registration form – and upon successful completion of that – be redirected to the Rango homepage. Hopefully everything will connect together and you'll be collecting more details about the users.

Class Based Views

In the previous subsection, we mentioned something called **class-based views**. Class based views are a different, and more elegant, but more sophisticated mechanism, for handling requests. Rather than taking a functional approach as we have done in this tutorial, that is, in our views.py we have written functions to handle each request, the class based approach mean inheriting and implementing a series methods to handle the requests. For example, rather than checking if a request was a get or a post, in the class based approach, you would need to implement a get() and post() method within the class. When your project and handlers become more complicated, using the Class based approach is more preferable. See the Django Documentation for more information about Class Based Views²⁰¹.

To get you started here is how we can convert the About view function to a class based view. First, in rango\views.py define a class called AboutView which inherits from View which we need to import from django.views:

²⁰¹https://docs.djangoproject.com/en/2.1/topics/class-based-views/

163

```
from django.views import View

class AboutView(View):
    def get(self, request):
        # view logic
        visitor_cookie_handler(request)
        return render(request, 'rango/about.html', context={'visits': request.sessio\n['visits']})
```

Next, in rango\urls.py, update the path, and import the AboutView from your views.

```
from rango.views import AboutView
...

urlpatterns = [
    ...
    # Updated path that points to the About View.
    path('about/', AboutView.as_view(), name='about'),
    ...
]
```

Now, for such a simple view it is doesn't really save much time or space, but now that you have the imported the classes, and get the idea you can now update more complex views, which need to handle both gets and posts. For example, we can create an AddCategoryView class based view to replace the add_category as shown below.

```
from django.utils.decorators import method_decorator

class AddCategoryView(View):

@method_decorator(login_required)

def get(self, request):
    form = CategoryForm()
    return render(request, 'rango/add_category.html', {'form': form})

@method_decorator(login_required)

def post(self, request):
    form = CategoryForm()
    form = CategoryForm(request.POST)
    if form.is_valid():
        form.save(commit=True)
```

```
return index(request)
else:
    print(form.errors)
return render(request, 'rango/add_category.html', {'form': form})
```

Notice that to ensure that users can only add categories if they are logged in, we needed to import method_decorator and then decorate the get and post methods with @method_decorator(login_required).

Next, in rango\urls.py we can import the class e.g. from rango.views import AboutView, AddCategoryView and update the path e.g. path('add_category/', AddCategoryView.as_view(), name='add_category'),. Without having to deal with the condition to test if the request is a post or not, we can more elegant code up how the view should respond in the different circumstances.

Additional Exercise

- Go through the Django Documentation and study how to create Class-Based Views.
- Update the Rango application to use Class-Based Views.
- Tweet how awesome you are and let us know @tangowithdjango.

Viewing your Profile

With the creation of a UserProfile object now complete, let's implement the functionality to allow a user to view his or her profile and edit it. The process is again pretty similar to what we've done before. We'll need to consider the following aspects:

- the creation of a new template, profile.html;
- creating a new view called profile() that uses the profile.html template; and
- mapping the profile() view to a new URL (/rango/profile).

We'll also need to provide a new hyperlink in Rango's base.html template to access the new view. For this solution, we'll be creating a generalised view that allows you to access the information of any user of Rango. The code will allow logged in users to also edit their profile; but only *their* profile - thus satisfying the requirements of the exercise.

Creating the Template

First, let's create a simple template for displaying a user's profile. The following HTML markup and Django template code should be placed within the new profile.html template within Rango's template directory.

```
{% extends 'rango/base.html' %}
{% load staticfiles %}
{% block title %}{{ selecteduser.username }} Profile{% endblock %}
{% block body_block %}
<div class="jumbotron p-4">
        <div class="container">
                 <h1 class="jumbotron-heading">{{selecteduser.username}} Profile</h1>
    </div>
</div>
<div class="container">
        <div class="row">
<img src="{{ MEDIA_URL }}{{userprofile.picture }}"</pre>
    width="300"
    height="300"
    alt="{{selecteduser.username}}" />
<br/>
<div>
    {% if selecteduser.username == user.username %}
        <form method="post" action="." enctype="multipart/form-data">
             {% csrf_token %}
            {{ form.as_p }}
            <input type="submit" value="Update" />
        </form>
    {% else %}
    <strong>Website:</strong> <a href="{{userprofile.website}}">
        {{userprofile.website}}</a>
    {% endif %}
</div>
<div id="edit_profile"></div>
</div>
</div>
{% endblock %}
```

Note that there are a few variables (selecteduser, userprofile and form) that we need to define in the template's context - we'll be doing so in the next section.

The fun part of this template is within the body_block block. The template shows the user's profile image at the top. Underneath, the template shows a form allowing the user to change his or her

details, which is populated from the form variable. This form however is *only shown* when the selected user matches the user that is currently logged in, thus only allowing the presently logged in user to edit his or her profile. If the selected user does not match the currently logged in user, then the selected user's website is displayed - but it cannot be edited.

You should also take not of the fact that we again use enctype="multipart/form-data" in the form due to the fact image uploading is used.

Creating the profile() View

Based upon the template created above, we can then implement a simple view to handle the viewing of user profiles and submission of form data. In Rango's views.py module, create a new class based view called ProfileView.

```
from rango.models import UserProfile
from django.contrib.auth.models import User
class ProfileView(View):
    def get_user_details(self, username):
       try:
            user = User.objects.get(username=username)
       except User.DoesNotExist:
            return redirect('index')
       userprofile = UserProfile.objects.get_or_create(user=user)[0]
        form = UserProfileForm({'website': userprofile.website, 'picture': userprofi\
le.picture})
       return (user, userprofile, form)
   @method_decorator(login_required)
   def get(self, request, username):
        (user, userprofile, form) = self.get_user_details(username)
       return render(request, 'rango/profile.html',
            {'userprofile': userprofile, 'selecteduser': user, 'form': form})
    @method_decorator(login_required)
    def post(self, request, username):
        (user, userprofile, form) = self.get_user_details(username)
        form = UserProfileForm(request.POST, request.FILES, instance=userprofile)
       if form.is_valid():
            form.save(commit=True)
            return redirect('profile', user.username)
```

```
else:
    print(form.errors)
return render(request, 'rango/profile.html',
    {'userprofile': userprofile, 'selecteduser': user, 'form': form})
```

This class based view requires that a user be logged in - hence the use of the <code>@method_decorator(login_required)</code> decorator, and we also need to import the <code>User</code> and <code>UserProfile</code> models. In the class, we created a helper method that both get and <code>post</code> use, so we dont repeat ourselves.

The helper methods begins by selecting the selected django.contrib.auth.User from the database - if it exists. If it doesn't, we perform a simple redirect to Rango's homepage rather than greet the user with an error message. We can't display information for a non-existent user! If the user does exist, we can select the user's UserProfile instance. If it doesn't exist, we can create a blank one. We then populate a UserProfileForm object with the selected user's details if we require it. The user, userprofile and populated form are then returned.

In the post method, we handle the case where a user wants to update their account information. So we extract information from the form into a UserProfileForm instance that is able to reference to the UserProfile model instance that it is saving to, rather than creating a new UserProfile instance each time. Remember, we are *updating*, not creating *new*. A valid form is then saved. An invalid form or a HTTP GET request triggers the rendering of the profile.html template with the relevant variables that are passed through to the template via its context.

Authentication Exercise

How can we change the code above to prevent unauthorised users from changing the details of a user account that isn't theirs? What conditional statement do we need to add to enforce this additional check?

Mapping the View to a URL

We then need to map our new ProfileView to a URL. First import the class, from rango.views import ProfileView, and then add in the path within the urlpatterns list.

```
path('profile/<username>/', ProfileView.as_view(), name='profile')
```

Note the inclusion of a username variable which is matched to anything after /profile/ - meaning that the URL /rango/profile/maxwelld90/ would yield a username of maxwelld90, which is in turn passed to the profile() view as parameter username. This is how we are able to determine what user the current user has selected to view.

Tweaking the Base Template

Everything should now be working as expected - but it'd be nice to add a link in Rango's base.html template to link the currently logged in user to their profile, providing them with the ability to view or edit it. In Rango's base.html template, find the code that lists a series of links in the navigation bar of the page when the *user is logged in*. Add the following hyperlink to this collection.

```
class="nav-item ">
<a class="nav-link" href="{% url 'rango:profile' user.username %}">Profile</a>
```

Rango's complete user profile page.

Listing all Users

Our final challenge is to create another page that allows one to view a list of all users on the Rango app. This one is relatively straightforward - we need to implement another template, view and URL mapping - but the view in this instance is very simplistic. We'll be creating a list of users registered to Rango - and providing a hyperlink to view their profile using the code we implemented in the previous section.

Creating a Template for User Profiles

In Rango's templates directory, create a template called <code>list_profiles.html</code>, within the file, add the following HTML markup and Django template code.

```
<div class="container">
        <div class="row">
    {% if userprofile_list %}
    <div class="panel-heading">
        <!-- Display search results in an ordered list -->
        <div class="panel-body">
            <div class="list-group">
                {% for listuser in userprofile_list %}
                <div class="list-group-item">
                    <h4 class="list-group-item-heading">
                        <a href="{% url 'rango:profile' listuser.user.username %}">
                            {{ listuser.user.username }}</a>
                    </h4>
                </div>
                {% endfor %}
            </div>
        </div>
    </div>
    {% else %}
        There are no users for the site.
    {% endif %}
</div>
</div>
{% endblock %}
```

This template is relatively straightforward - we created a series of <div> tags using various Bootstrap classes to style the list. For each user, we display their username and provide a link to their profile page. Notice since we pass through a list of UserProfile objects, to access the username of the user, we need to go view the user property of the UserProfile object to get username.

Creating the View

With our template created, we can now create the corresponding view that selects all users from the UserProfile model. We also make the assumption that the current user must be logged in to view the other users of Rango. The following view list_profiles() can be added to Rango's views.py module to provide this functionality.

Mapping the View and Adding a Link

Our final step is to map a URL to the new list_profiles() view. Add the following to the urlpatterns list in Rango's urls.py module to do this.

```
path('profiles/', views.list_profiles, name='list_profiles'),
```

We could also add a new hyperlink to Rango's base.html template, allowing users who are logged in to view the new page. Like before, add the following markup to the base template which provides links only to logged in users.

```
class="nav-item ">
<a class="nav-link" href="{% url 'rango:list_profiles' %}">List Profiles</a>
```

With this link added you should be able to view the list of user profiles, and view specific profiles.

Profile Page Exercise

- Update the profile list to include a thumbnail of the user's profile picture.
- If a user does not have a profile picture, then insert a substitute picture by using the service provide by LoremPixel²⁰² that lets you automatically generate images.

Hint: you can use 203 from LoremPixel to get a picture of people that is 64x64 in size. Note that it might take a few seconds for the picture to download.

²⁰²ttp://lorempixel.com/

²⁰³http://lorempixel.com/64/64/people/

JQuery and Django

JQuery rocks! JQuery²⁰⁴ is a library written in JavaScript that lets you access the power of JavaScript without too much pain. This is because a few lines of JQuery often encapsulates hundreds of lines of JavaScript. Also, JQuery provides a suite of functionality that is mainly focused on manipulating HTML elements. In this chapter, we will describe:

- how to incorporate JQuery within your Django app;
- · explain how to interpret JQuery code; and
- and provide a number of small examples.

Including JQuery in Your Django Project/App

In your *base* template include a reference to JQuery (we will be using version 3.3.1). You can do these either by including a reference directly to the JQuery site:

```
<script src="https://code.jquery.com/jquery-3.3.1.min.js" crossorigin="anonymous"></script>
```

or if you have downloaded and saved a copy to your static directory, then you can reference it as follows:

```
<script src="{% static "js/jquery-3.3.1.min.js" %}"></script>
<script src="{% static "js/rango-jquery.js" %}"></script>
```

Note, that if you already done the Bootstrap Chapter, the the SLIM version of the JQuery library has already been imported, right at the bottom of the template. You will need to change it, otherwise you wont have access to the functions needed to perform AJAX calls in the next chapter!

Make sure you have your static files set up (see Chapter Templates and Static Media) and that you have '{% load staticfiles %} at the top of base.html'.

Also, add a reference to a script called rango-jquery. js after the JQuery library import.

```
<script src="{% static "js/rango-jquery.js" %}"></script>
```

In the static directory, create a *js* directory and place the JQuery JavaScript file (jquery.js) here along with an file called rango-jquery.js. This script will house our JavaScript code. In rango-jquery.js, add the following JavaScript:

²⁰⁴https://jquery.com/

JQuery and Django 172

```
$(document).ready(function() {
    // JQuery code to be added in here.
});
```

This piece of JavaScript utilises JQuery. It first selects the document object (with \$(document)), and then makes a call to ready(). Once the document is ready (i.e. the complete page is loaded), the anonymous function denoted by function() { } will be executed. It is pretty typical, if not standard, to wait until the document has been finished loading before running the JQuery functions. Otherwise, the code may begin executing before all the HTML elements have been downloaded. See the JQuery Documentation on Ready²⁰⁵ for more details.

Select and Act Pattern

JQuery requires you to think in a more *functional* programming style, as opposed to the typical JavaScript style which is often written in a more *procedural* programming style. For all the JQuery commands, they follow a similar pattern: **Select and Act**. Select an element, and then perform some action on/with the element.

Example Popup Box on Click

In this example, we want to show you the difference between doing the same functionality in standard JavaScript versus JQuery. In your about .html template, add the following piece of code:

As you can see, we are assigning the function alert() to the onClick handler of the button. Load up the about page, and try it out. Now lets do it using JQuery, by first adding another button:

```
<button class="btn btn-primary" id="about-btn">
    Click Me - I'm JavaScript on Ice
</button>
```

Notice that there is no JavaScript code associated with the button currently. We will be doing that with the following code added to rango-jquery. js:

²⁰⁵http://api.jquery.com/ready/

JQuery and Django 173

```
$(document).ready( function() {
    $("#about-btn").click( function(event) {
        alert("You clicked the button using JQuery!");
    });
});
```

Reload the page, and try it out. Hopefully, you will see that both buttons pop up an alert.

The JQuery/JavaScript code here first selects the document object, and when it is ready, it executes the functions within its body, i.e. $\c^*=btn''$.click(). This code selects the element in the page with an id equal to about-btn, and then programatically assigns to the click event the alert() function.

At first, you might think that JQuery is rather cumbersome, as it requires us to include a lot more code to do the same thing. This may be true for a simple function like alert(). For more complex functions, it is much cleaner as the JQuery/JavaScript code is maintained in a separate file. This is because we assign the event handler at runtime rather than statically within the code. We achieve separation of concerns between the JQuery/JavaScript code and the HTML markup.

Keep Them Separated

Separation of Concerns²⁰⁶ is a design principle that is good to keep in mind. In terms of web apps, the HTML is responsible for the page content; CSS is used to style the presentation of the content, while JavaScript is responsible for how the user can interact with the content, and manipulating the content and style.

By keeping them separated, you will have cleaner code and you will reduce maintenance woes in the future.

Put another way, never mix, never worry!

Selectors

There are different ways to select elements in JQuery. The above example shows how the # selector can be used to find elements with a particular id in your HTML document. To find classes, you can use the . selector, as shown in the example below.

```
$(".ouch").click( function(event) {
    alert("You clicked me! ouch!");
});
```

Then all elements in the document that have the class="ouch" would be selected, and assigned to its on click handler, the alert() function. Note that all the elements would be assigned the same function.

HTML tags can also be selected by referring to the tag in the selector:

²⁰⁶https://en.wikipedia.org/wiki/Separation_of_concerns

JQuery and Django 174

```
$("p").hover( function() {
    $(this).css('color', 'red');
},
function() {
    $(this).css('color', 'black');
});
```

Add this JavaScript to your rango-jquery.js, and then in the about.html template, add a paragraph, This text is for a JQuery Example. Try it out, go to the about page and hover over the text.

Here, we are selecting all the p HTML elements, and on hover we are associated two functions, one for on hover, and the other for hover off. You can see that we are using another selector called, this, which selects the element in question, and then sets its colour to red or blue respectively. Note that the JQuery hover() function takes two functions²⁰⁷, and the JQuery click()²⁰⁸ function requires the event to be passed through.

Try adding the above code your rango-jquery. js file, making sure it is within the \$(document).ready() function. What happens if you change the \$(this) to \$(p)?

Hovering is an example of a mouse move event. For descriptions on other such events, see the JQuery API documentation²⁰⁹.

DOM Manipulation Example

In the above example, we used the hover function to assign an event handler to the on hover event, and then used the css function to change the colour of the element. The css function is one example of DOM manipulation, however, the standard JQuery library provides many other ways in which to manipulate the DOM. For example, we can add classes to elements, with the addClass function:

```
$("#about-btn").removeClass('btn-primary').addClass('btn-success');
```

This will select the element with id #about-btn, and first remove the btn-primary class which makes the button blue, and then adds the btn-success class to make it green.

It is also possible to access the inner HTML of a particular element. For example, lets put a div in the about.html template:

```
<div id="msg">Hello - I'm here for a JQuery Example too</div>
```

Then add the following JQuery to rango-jquery.js:

²⁰⁷http://api.jquery.com/hover/

²⁰⁸http://api.jquery.com/click/

²⁰⁹http://api.jquery.com/category/events/mouse-events/

JQuery and Django 175

```
$("#about-btn").click( function(event) {
    msgstr = $("#msg").html()
    msgstr = msgstr + "ooo"
    $("#msg").html(msgstr)
});
```

When the element with id #about-btn is clicked, we first get the HTML inside the element with id msg and append "o" to it. We then change the HTML inside the element by calling the html() function again, but this time passing through string msgstr to replace the HTML inside that element.

In this chapter, we have provided a very rudimentary guide to using JQuery and how you can incorporate it within your Django app. From here, you should be able to understand how JQuery operates and experiment with the different functions and libraries provided by JQuery and JQuery developers. In the next chapter, we will be using JQuery to help provide AJAX functionality within Rango.

AJAX in Django with JQuery

AJAX essentially is a combination of technologies that are integrated together to reduce the number of page loads. Instead of reloading the full page, only part of the page or the data in the page is reloaded. If you haven't used AJAX before or would like to know more about it before using it, check out the AJAX resources at the Mozilla website²¹⁰.

To simplify the AJAX requests, we will be using the JQuery library. Note that if you are using the Twitter CSS Bootstrap toolkit then JQuery will already be added in. We are using JQuery version 3.3.1²¹¹. Otherwise, download the JQuery library and include it within your application, i.e. save it within your project into the static/js/ directory (see JQuery Chapter).

AJAX based Functionality

To modernise the Rango application, let's add in a number of features that will use AJAX, such as:

- adding a "Like Button" to let registered users "like" a particular category;
- adding inline category suggestions so that when a user types they can quickly find a category;
 and
- adding an "Add Button" to let registered users quickly and easily add a Page to the Category when they perform a search.

Create a new file, called rango-ajax. js and add it to your static/js/ directory. Then in your base template include:

```
<script src="{% static "js/rango-ajax.js" %}"></script>
```

Here we assume you have downloaded a version of the JQuery library or you link to it as per the instructions in the JQuery Chapter.

Now that we have created a file to put our client side AJAX code, we can now get to work.

Add a Like Button

It would be nice to let users, who are registered, denote that they "like" a particular category. In the following workflow, we will let users "like" categories, but we will not be keeping track of what categories they have "liked". A registered user could click the like button multiple times if they refresh the page. If we wanted to keep track of their likes, we would have to add in an additional model, and other supporting infrastructure, but we'll leave that as an exercise for you to complete.

 $^{^{210}} https://developer.mozilla.org/en-US/docs/AJAX$

²¹¹https://code.jquery.com/jquery-3.3.1.slim.min.js

Workflow

To let users "like" certain categories, undertake the following workflow.

- In the category.html template:
 Add in a "Like" button with id="like".
 - Add in a template tag to display the number of likes: {{% category.likes %}}
 - Place this inside a div with id="like_count", i.e. <div id="like_count">{{ category.likes
 - This sets up the template to capture likes and to display likes for the category.
 - Note, since the category() view passes a reference to the category object, we can use that
- to access the number of likes, with $\{\{\text{ category.likes }\}\}\$ in the template Create a view called, like_category which will examine the request and pick out the
 - category/. The GET request will then be rango/like_category/?category_id=XXX
 - Instead of returning a HTML page have this view will return the new total number of likes for that category.
- Now in rango-ajax.js add the JQuery code to perform the AJAX GET request.
 If the request is successful, then update the #like_count element, and hide the like button.

Updating Category Template

To prepare the template, we will need to add in the "like" button with id="like" and create a <div> to display the number of likes {{% category.likes %}}. To do this, add the following <div> to the category.html template after the <h1>{{ category.name }}</h1> tag.

```
<strong id="like_count">{{ category.likes }}</strong> people like this category
{% if user.is_authenticated %}
    <button id="likes" data-catid="{{category.id}}"</pre>
        class="btn btn-primary btn-sm" type="button">
        <span data-feather="thumbs-up"></span>
        Like
    </button>
{% endif %}
</div>
```

Notice that we used the thumnbs up icon from Feather²¹², e.g. .

Create a Like Category View

Create a new view called, like_category in rango/views.py which will examine the request and pick out the category_id and then increment the number of likes for that category.

²¹²https://feathericons.com/

from django.contrib.auth.decorators import login_required

```
@login_required
def like_category(request):
    cat_id = None
    if request.method == 'GET':
        cat_id = request.GET['category_id']
        likes = 0
    if cat_id:
        cat = Category.objects.get(id=int(cat_id))
        if cat:
            likes = cat.likes + 1
             cat.likes = likes
             cat.save()
    return HttpResponse(likes)
```

On examining the code, you will see that we are only allowing authenticated users to even access this view because we have put a decorator @login_required before our view.

Note that the view assumes that a variable category_id has been passed to it via a GET request so that we can identify the category to update. In this view, we could also track and record that a particular user has "liked" this category if we wanted - but we are keeping it simple to focus on the AJAX mechanics.

Don't forget to add in the URL mapping, into rango/urls.py. Update the urlpatterns by adding in:

```
path('like$', views.like_category, name='like_category'),
```

Making the AJAX request

Now in "rango-ajax.js" you will need to add some JQuery code to perform an AJAX GET request. Add in the following code:

This piece of JQuery/JavaScript will add an event handler to the element with id #likes, i.e. the button. When clicked, it will extract the category ID from the button element, and then make an AJAX GET request which will make a call to /rango/like/ encoding the category_id in the request. If the request is successful, then the HTML element with ID like_count (i.e. the) is updated with the data returned by the request, and the HTML element with ID likes (i.e. the <button>) is hidden.

There is a lot going on here, and getting the mechanics right when constructing pages with AJAX can be a bit tricky. Essentially, an AJAX request is made given our URL mapping when the button is clicked. This invokes the <code>like_category</code> view that updates the category and returns the new number of likes. When the AJAX request receives the response, it updates parts of the page, i.e. the text and the button. The <code>#likes</code> button is hidden.

Adding Inline Category Suggestions

It would be really neat if we could provide a fast way for users to find a category, rather than browsing through a long list. To do this we can create a suggestion component that lets users type in a letter or part of a word, and then the system responds by providing a list of suggested categories, that the user can then select from. As the user types a series of requests will be made to the server to fetch the suggested categories relevant to what the user has entered.

Workflow

To do this you will need to do the following.

- Create a parameterised function called get_category_list(max_results=0, starts_with='') that returns all the categories starting with starts_with if max_results=0 otherwise it returns up to max_results categories.
 - The function returns a list of category objects annotated with the encoded category denoted by the attribute, url
- Create a view called *suggest_category* which will examine the request and pick out the category query string.
 - Assume that a GET request is made and attempt to get the *query* attribute.
 - If the query string is not empty, ask the Category model to get the top 8 categories that start with the query string.
 - The list of category objects will then be combined into a piece of HTML via template.
 - Instead of creating a template called suggestions.html re-use the cats.html as it will be displaying data of the same type (i.e. categories).
 - To let the client ask for this data, you will need to create a URL mapping; let's call it *suggest*.

With the URL mapping, view, and template in place, you will need to update the base.html template to provide a category search box, and then add in some JavaScript/JQuery code to link up everything so that when the user types the suggested categories are displayed.

In the base.html template modify the sidebar block so that a div with an id="cats" encapsulates the categories being presented. The JQuery/AJAX will update this element. Before this <div> add an input box for a user to enter the letters of a category, i.e.:

```
id="search" class="form-control ds-input"
id="search-input" placeholder="Search..." >
```

With these elements added into the templates, you can add in some JQuery to update the categories list as the user types.

- Associate an on keypress event handler to the input with id="suggestion"
- \$('#suggestion').keyup(function(){ ... })
- On keyup, issue an ajax call to retrieve the updated categories list
- Then use the JQuery .get() function i.e. \$(this).get(...)
- If the call is successful, replace the content of the <div> with id="cats" with the data received.
- Here you can use the JQuery .html() function i.e. \$('#cats').html(data)

Exercise

• Update the population script by adding in the following categories: Pascal, Perl, PHP, Prolog, PostScript and Programming. These additional categories will make the demo of the inline category suggestion functionality more impressive.

Parameterising get_category_list()

In this helper function, we use a filter to find all the categories that start with the string supplied. The filter we use will be <code>istartwith</code>, this will make sure that it doesn't matter whether we use uppercase or lowercase letters. If it on the other hand was important to take into account whether letters was uppercase or not you would use <code>startswith</code> instead.

```
def get_category_list(max_results=0, starts_with=''):
    cat_list = []
    if starts_with:
        cat_list = Category.objects.filter(name__istartswith=starts_with)

if max_results > 0:
    if len(cat_list) > max_results:
        cat_list = cat_list[:max_results]

return cat_list
```

Create a Suggest Category View

Using the get_category_list() function, we can now create a view that returns the top eight matching results as follows:

```
def suggest_category(request):
    cat_list = []
    starts_with = ''

if request.method == 'GET':
        starts_with = request.GET['suggestion']

cat_list = get_category_list(8, starts_with)
    if len(cat_list) == 0:
        cat_list = Category.objects.order_by('-likes')
```

Note here we are reusing the rango/cats.html template.

Mapping the View to URL

Add the following code to urlpatterns in rango/urls.py:

```
path('suggest/', views.suggest_category, name='suggest_category'),
```

Updating the Base Template

In the base template, in the sidebar <nav>, update the HTML template so that you have:

Here, we have added in an input box with id="suggestion" and div with id="cats" in which we will display the response. We don't need to add a button as we will be adding an event handler on keyup to the input box that will send the suggestion request.

Add AJAX to Request Suggestions

Add the following JQuery code to the js/rango-ajax.js:

```
$('#suggestion').keyup(function(){
   var query;
   query = $(this).val();
   $.get('/rango/suggest/', {suggestion: query}, function(data){
        $('#cats').html(data);
   });
});
```

Here, we attached an event handler to the HTML input element with id="suggestion" to trigger when a keyup event occurs. When it does, the contents of the input box is obtained and placed into the query variable. Then a AJAX GET request is made calling /rango/category_suggest/ with the query as the parameter. On success, the HTML element with id="cats" (i.e. the <div>) is updated with the category list HTML.

An example of the inline category suggestions. Notice how the suggestions populate and change as the user types each individual character.

Exercises

To let registered users quickly and easily add a Page to the Category put an "Add" button next to each search result. - Update the category.html template: - Add a small button next to each search result (if the user is authenticated), garnish the button with the title and URL data, so that the JQuery can pick it out. - Put a <div> with id="page" around the pages in the category so that it can be updated when pages are added. - Remove that link to add button, if you like. - Create a view auto_add_page that accepts a parameterised GET request (title, url, catid) and adds it to the category. - Map an URL to the view url(r'^add/\$', views.auto_add_page, name='auto_add_page'), - Add an event handler to the add buttons using JQuery - when added hide the button. The response could also update the pages listed on the category page, too.

We have included the following code fragments to help you complete the exercises above. The HTML template code for category.html that inserts a button, and crucially keeps a record of the category that the button is associated with.

The JQuery code that adds the click event handler to every button with the class rango-add:

The view code that handles the adding of a link to a category:

```
@login_required
def auto_add_page(request):
   cat_id = None
   url = None
   title = None
   context_dict = {}
    if request.method == 'GET':
        cat_id = request.GET['category_id']
        url = request.GET['url']
        title = request.GET['title']
        if cat_id:
            category = Category.objects.get(id=int(cat_id))
            p = Page.objects.get_or_create(category=category,
                title=title, url=url)
            pages = Page.objects.filter(category=category).order_by('-views')
            # Adds our results list to the template context under name pages.
            context_dict['pages'] = pages
   return render(request, 'rango/page_list.html', context_dict)
```

The HTML template markup for the new template page_list.html:

```
{% if pages %}
   <u1>
       {% for page in pages %}
 3
       class="list-group-item">
            <a href="{% url 'rango:goto' %}?page_id={{page.id}}">{{ page.title }}</a>
5
           {% if page.views > 1 %}
 6
               ({{ page.views }} views)
 7
           {% elif page.views == 1 %}
8
9
               ({{ page.views }} view)
           {% endif %}
10
       11
       {% endfor %}
12
   13
   {% else %}
14
        <strong>No pages currently in category.
15
   {% endif %}
16
```

Finally, don't forget to add in the URL mapping: $path('add/', views.auto_add_page, name='auto_add_page'),$.

If all has gone well, hopefully, your Rango application will be looking something like screenshots below. But don't stop now, get on with the next chapters and deploy your project!

The main index page of the Rango application.

The category page with the Add Button feature.

It is good practice to get into the habit of writing and developing tests. A lot of software engineering is about writing and developing tests and test suites in order to ensure the software is robust. Of course, most of the time, we are too busy trying to build things to bother about making sure that they work. Or too arrogant to believe it would fail.

According to the Django Tutorial²¹³, there are numerous reasons why you should include tests.

- Test will save you time: a change in a complex system can cause failures in unpredictable places.
- Tests don't just identify problems, they prevent them: tests show where the code is not meeting expectations.
- Test make your code more attractive: "Code without tests is broken by design" Jacob Kaplan-Moss, one of Django's original developers.
- Tests help teams work together: they make sure your team doesn't inadvertently break your code.

According to the Python Guide²¹⁴, there are a number of general rules you should try to follow when writing tests. Below are some main rules.

- Tests should focus on one small bit of functionality
- Tests should have a clear purpose
- Tests should be independent.
- Run your tests, before you code, and before your commit and push your code.
- Even better create a hook that tests code on push.
- Use long and descriptive names for tests.

Testing in Django

Currently this chapter provides the very basics of testing and follows a similar format to the Django Tutorial²¹⁵, with some additional notes. We hope to expand this further in the future.

Running Tests

With Django is a suite of functionality to test apps built. You can test your Rango app by issuing the following command:

 $^{^{213}} https://docs.djangoproject.com/en/1.9/intro/tutorial05/$

 $^{^{\}tt 214} http://docs.python\text{-}guide.org/en/latest/writing/tests/$

²¹⁵https://docs.djangoproject.com/en/1.9/intro/tutorial05/

```
$ python manage.py test rango
Creating test database for alias 'default'...
Ran 0 tests in 0.000s
OK
Destroying test database for alias 'default'...
```

This will run through the tests associated with the Rango app. At the moment, nothing much happens. That is because you may have noticed the file rango/tests.py only contains an import statement. Every time you create an application, Django automatically creates such a file to encourage you to write tests.

From this output, you might also notice that a database called default is referred to. When you run tests, a temporary database is constructed, which your tests can populate, and perform operations on. This way your testing is performed independently of your live database.

Testing the models in Rango

Let's create a test. In the Category model, we want to ensure that views are either zero or positive, because the number of views, let's say, can never be less than zero. To create a test for this we can put the following code into rango/tests.py:

```
from django.test import TestCase
from rango.models import Category

class CategoryMethodTests(TestCase):
    def test_ensure_views_are_positive(self):
        """
        ensure_views_are_positive should results True for categories
        where views are zero or positive
        """
        cat = Category(name='test',views=-1, likes=0)
        cat.save()
        self.assertEqual((cat.views >= 0), True)
```

The first thing you should notice, if you have not written tests before, is that we have to inherit from TestCase. The naming over the method in the class also follows a convention, all tests start with test_ and they also contain some type of assertion, which is the test. Here we are checking if the values are equal, with the assertEqual method, but other types of assertions are also possible. See the Python 2 Documentation on unit tests²¹⁶ or the Python 3 Documentation on unit tests²¹⁷ for

²¹⁶https://docs.python.org/2/library/unittest.html

²¹⁷https://docs.python.org/3/library/unittest.html

other commands (i.e. assertItemsEqual, assertListEqual, assertDictEqual, etc). Django's testing machinery is derived from Python's but also provides a number of other asserts and specific test cases.

Now let's run the test:

As we can see this test fails. This is because the model does not check whether the value is less than zero or not. Since we really want to ensure that the values are non-zero, we will need to update the model to ensure that this requirement is fulfilled. Do this now by adding some code to the <code>save()</code> method of the <code>Category</code> model. The code should check the value of <code>views</code> attribute, and update it accordingly. A simple conditional check of <code>self.views</code> where it is less than zero should suffice here.

Once you have updated your model, you can now re-run the test, and see if your code now passes it. If not, try again.

Let's try adding another test that ensures an appropriate slug line is created, i.e. one with dashes, and in lowercase. Add the following code to rango/tests.py:

```
def test_slug_line_creation(self):
    """
    slug_line_creation checks to make sure that when we add
    a category an appropriate slug line is created
    i.e. "Random Category String" -> "random-category-string"
    """
    cat = cat('Random Category String')
    cat.save()
    self.assertEqual(cat.slug, 'random-category-string')
```

Does your code still work?

Testing Views

So far we have written tests that focus on ensuring the integrity of the data housed in the models. Django also provides testing mechanisms to test views. It does this with a mock client, that internally makes a calls a Django view via the URL. In the test you have access to the response (including the HTML) and the context dictionary.

Let's create a test that checks that when the index page loads, it displays the message that There are no categories present, when the Category model is empty.

```
from django.core.urlresolvers import reverse

class IndexViewTests(TestCase):

    def test_index_view_with_no_categories(self):
        """

        If no questions exist, an appropriate message should be displayed.
        """

        response = self.client.get(reverse('index'))
        self.assertEqual(response.status_code, 200)
        self.assertContains(response, "There are no categories present.")
        self.assertQuerysetEqual(response.context['categories'], [])
```

First of all, the Django TestCase has access to a client object, which can make requests. Here, it uses the helper function reverse to look up the URL of the index page. Then it tries to get that page, where the response is stored. The test then checks a number of things: whether the page loaded OK, whether the response HTML contains the phrase "There are no categories present.", and whether the context dictionary contains an empty categories list. Recall that when you run tests, a new database is created, which by default is not populated.

Let's now check the resulting view when categories are present. First add a helper method.

```
from rango.models import Category
def add_cat(name, views, likes):
   c = Category.objects.get_or_create(name=name)[0]
   c.views = views
   c.likes = likes
   c.save()
    return c
Then add another method to the class IndexViewTests(TestCase):
def test_index_view_with_categories(self):
    Check to make sure that the index has categories displayed
   add_cat('test',1,1)
   add_cat('temp',1,1)
   add_cat('tmp',1,1)
   add_cat('tmp test temp',1,1)
   response = self.client.get(reverse('index'))
    self.assertEqual(response.status_code, 200)
    self.assertContains(response, "tmp test temp")
```

num_cats =len(response.context['categories'])

In this test, we populate the database with four categories, and then check that the loaded page contains the text tmp test temp and if the number of categories is equal to 4. Note that this makes three checks, but is only considered to be one test.

Testing the Rendered Page

self.assertEqual(num_cats , 4)

It is also possible to perform tests that load up the application and programmatically interact with the DOM elements on the HTML pages by using either Django's test client and/or Selenium, which is are "in-browser" frameworks to test the way the HTML is rendered in a browser.

Coverage Testing

Code coverage measures how much of your code base has been tested, and how much of your code has been put through its paces via tests. You can install a package called coverage via with pip

install coverage that automatically analyses how much code coverage you have. Once you have coverage installed, run the following command:

```
$ coverage run --source='.' manage.py test rango
```

This will run through all the tests and collect the coverage data for the Rango application. To see the coverage report you need to then type:

\$ coverage report

Name	Stmts	Miss	Cover
manage	6	0	100%
populate	33	33	0%
rango/init	0	0	100%
rango/admin	7	0	100%
rango/forms	35	35	0%
rango/migrations/0001_initial	5	0	100%
rango/migrations/0002_auto_20141015_1024	5	0	100%
rango/migrations/0003_category_slug	5	0	100%
rango/migrations/0004_auto_20141015_1046	5	0	100%
rango/migrations/0005_userprofile	6	0	100%
rango/migrations/init	0	0	100%
rango/models	28	3	89%
rango/tests	12	0	100%
rango/urls	12	12	0%
rango/views	110	110	0%
tango_with_django_project/init	0	0	100%
tango_with_django_project/settings	28	0	100%
tango_with_django_project/urls	9	9	0%
tango_with_django_project/wsgi	4	4	0%
TOTAL	310	206	34%

We can see from the above report that critical parts of the code have not been tested, i.e. rango/views. The coverage package has many more features²¹⁸ that you can explore to make your tests even more comprehensive!

²¹⁸http://nedbatchelder.com/code/coverage/

Exercises

Lets say that we want to extend the Page to include two additional fields, last_visit and first_visit that will be of type timedate.

- Update the model to include these two fields.
- Update the add page functionality, and the goto functionality.
- Add in a test to ensure the last visit or first visit is not in the future.
- Add in a test to ensure that the last visit equal to or after the first visit.
- Run through Part Five of the official Django Tutorial²¹⁹ to learn more about testing.
- Check out the tutorial on test driven development by Harry Percival²²⁰.

 $^{^{219}\}mbox{https://docs.djangoproject.com/en/1.9/intro/tutorial05/}$ $^{220}\mbox{http://www.tdd-django-tutorial.com}$

This chapter provides a step-by-step guide on how to deploy your Django application on PythonAnywhere²²¹, which is an online IDE and web hosting service. The service provides in-browser access to the server-based Python and Bash command line interfaces, meaning you can interact with PythonAnywhere's servers just like you would with a regular terminal instance on your own computer. Currently, PythonAnywhere are offering a free beginner account, which is perfect to get started. It provides you up with an adequate amount of storage space and CPU time to get one Django application up and running.

Go Git It!

You can do this chapter independently as we have already implemented Rango and it is available from GitHub. If you haven't used Git/GitHub before, you can check out our chapter on using Git).

Creating a PythonAnywhere Account

First, sign up for a Beginner PythonAnywhere account²²² and take the seven step tour to get familar with the PythonAnywhere interface. If your application takes off and becomes popular, you can always upgrade your account at a later stage to gain more storage space and CPU time along with a number of other benefits - such as hosting specific domains and SSH abilities, for example.

Once your account has been created, and you have confirmed your email, you will have your own little slice of the World Wide Web at http://<username>.pythonanywhere.com, where <username> is your PythonAnywhere username. It is from this URL that your hosted application will be available.

The PythonAnywhere Web Interface

The PythonAnywhere web interface contains a *dashboard* which in turn provides a series of different components allowing you to manage your application. The components as illustrated in the figure below include:

- Consoles, allowing you to create and interact with Python and Bash console instances;
- Files, which allows you to upload to and organise files within your disk quota; and

²²¹https://www.pythonanywhere.com/?affiliate_id=000116e3

²²²²https://www.pythonanywhere.com/?affiliate_id=000116e3

• Web Apps, allowing you to configure settings for your hosted web application;

Other components exist, such as *Notebooks*, but we won't be using them here – we'll be working primarily with the *consoles* and *web* components. The PythonAnywhere Wiki²²³ provides a series of detailed explanations on how to use the other components if you are interested in finding out more.

The PythonAnywhere dashboard, showing the main components you can use.

Creating a Virtual Environment

As part of its standard default Bash environment, PythonAnywhere comes with Python 2.7+ and a number of pre-installed Python Packages (including *Django *). But, since we are using a different setup, we need to setup the Python 3 version, manually, through a virtual environment.

First, open a Bash console. If you run python --version then you will see that the native Python is 2.7+, so to create a virtual environment that uses Python 3.6+, issue the following command:

```
11:45 ~ $ mkvirtualenv --python=python3.6 rango
Running virtualenv with interpreter /usr/bin/python3.6
New python executable in /home/<username>/.virtualenvs/rango/bin/python3.6
Also creating executable in /home/<username>/.virtualenvs/rango/bin/python
Installing setuptools, pip, wheel...done.
virtualenvwrapper creating /home/<username>/.virtualenvs/.../predeactivate
virtualenvwrapper creating /home/<username>/.virtualenvs/.../postdeactivate
virtualenvwrapper creating /home/<username>/.virtualenvs/.../postactivate
virtualenvwrapper creating /home/<username>/.virtualenvs/.../postactivate
virtualenvwrapper creating /home/<username>/.virtualenvs/.../postactivate
virtualenvwrapper creating /home/<username>/.virtualenvs/.../get_env_details
```

Above we have used Python 3.6, but you can check which version of Python you are using and use that instead. Also, note that where it shows <username> that will be replaced with your username. The process of creating the virtual environment will take a little while to complete, after which you will be presented with a slightly different prompt.

```
(rango) 11:45 ~ $
```

Note the inclusion of (rango) compared to the previous command prompt. This signifies that the rango virtual environment has been activated, so any package installations will be done within that virtual environment, leaving the wider system setup alone. If you issue the command 1s -1a, you

²²³https://www.pythonanywhere.com/wiki/

will see that a directory called .virtualenvs has been created. This is the directory in which all of your virtual environments and associated packages will be stored. To confirm the setup, issue the command which pip. This will print the location in which the active pip binary is located - hopefully within .virtualenvs and rango, as shown in the example below.

```
/home/<username>/.virtualenvs/test/bin/pip
```

To see what packages are already installed, enter pip list. Now we can customise the virtual environment by installing the required packages for our Rango application. Install all the required packages, by issuing the following commands.

```
$ pip install -U django==2.1.5
$ pip install pillow
$ pip install django-registration-redux
$ pip install bcrypt
$ pip install requests
```

**Ensure that you replace the version of Django specified above with the one you are using for development. Here we have used verison 2.1.5, but no doubt a newer verison is available (and o). Not using the same verison as your development machine could lead to some wierd errors and exceptions - which will drive you crazy. To ensure you have the same setup, we recommend using pip freeze > requirements.txt on your local development machine. This will note down all the packages in your current development environment. Then on PythonAnywhere, you can run pip install -r requirements.txt to install all the packages in one go.

Waiting to Download...

Installing all theses packages may take some time, so you can relax, call a friend, or tweet about our tutorial @tangowithdjango!

Once installed, check if Django has been installed with the command which django-admin.py. You should receive output similar to the following example.

/home/<username>/.virtualenvs/rango/bin/django-admin.py

Virtual Environments on PythonAnywhere

PythonAnywhere also provides instructions on how to setup virtual environments. Check out their Wiki documentation for more information²²⁴.

²²⁴https://help.pythonanywhere.com/pages/VirtualEnvForNewerDjango

Virtual Environment Switching

Moving between virtual environments can be done pretty easily. PythonAnywhere should have this covered for you. Below, we provide you with a quick tutorial on how to switch between virtual environments.

At your terminal, you can launch into a pre-existing virtual environment with the workon command. For example, to load up the rango environment, enter:

```
11:48 ~ $ workon rango
```

where rango can be replaced with the name of the virtual environment you wish to use. Your prompt should then change to indicate you are working within a virtual environment. This is shown by the addition of (rango) to your prompt.

```
(rango) 11:49 ~ $
```

You can then leave the virtual environment using the deactivate command. Your prompt should then be missing the (rango) prefix, with an example shown below.

```
(rango) 11:49 ~ $ deactivate
11:51 ~ $
```

Cloning your Git Repository

Now that your virtual environment for Rango is all setup, you can now clone your Git repository to obtain a copy of your project's files. Clone your repository by issuing the following command from your home directory:

```
$ git clone https://<USERNAME>:<PASSWORD>@github.com/<OWNER>/<REPO_NAME>.git
```

where you replace - <USERNAME> with your GitHub username; - <PASSWORD> with your GitHub password; - <OWNER> with the username of the person who owns the repository; and - <REPO_NAME> with the name of your project's repository.

Setting Up the Database

With your files cloned, you must then prepare your database. We'll be using the populate_rango.py module that we created earlier in the book. As we'll be running the module, you must ensure that you are using the rango virtual environment (i.e. you see (rango) as part of your prompt - if not, invoke workon rango). From your home directory, move into the tango_with_django_19 directory, then to the code directory. This directory will be named after your git repository, so the name may differ. For example, if you called your repository twd, the directory will also be called twd. Depending upon how you configured your repository, you should also cd into the directory with manage.py in it - tango_with_django_project. Now issue the following commands.

```
(rango) 16:55 ~/tango_with_django $ python manage.py makemigrations rango
(rango) 16:55 ~/tango_with_django $ python manage.py migrate
(rango) 16:56 ~/tango_with_django $ python populate_rango.py
(rango) 16:57 ~/tango_with_django $ python manage.py createsuperuser
```

As discussed earlier in the book, the first command creates the migrations for the rango app, then the migrate command creates the *SQLlite3* database. Once the database is created, the database can be populated and a superuser created.

Setting up Your Web Application

Now that the database is setup, we need to configure the PythonAnywhere *NGINX*²²⁵ Web server to serve up your application. From PythonAnywhere's dashboard, open up the *Web Apps* tab. On the left of the page that appears, click *Add a new web app*.

A popup box will then appear. Follow the instructions on-screen, and when the time comes, select the *manual configuration* option and complete the wizard. Make sure you select the same Python version as the one you selected earlier.

In a new tab or window in your Web browser, go visit your PythonAnywhere subdomain at the address http://<username>.pythonanywhere.com. You should be presented with the default Hello, World! webpage, as shown below. This is because the WSGI script is currently serving up this page, and not your Django application. This is what we need to change next.

The default PythonAnywhere hello world webpage.

Configure the Virtual Environment

To set the virtual environment for your app, navigate again to the *Web* tab in PythonAnywhere's interface. From there, scroll all the way down under you see the heading *Virtualenv*.

Enter in the path to your virtual environment. Assuming you created a virtual environment called rango the path would be:

/home/<username>/.virtualenvs/rango

You can start a console to check if it is successful.

Now in the *Code* section, you can set the path to your web applications source code.

²²⁵https://www.nginx.com/resources/wiki/

```
/home/<username>/<path-to>/tango_with_django_project/
```

Note that this path should be pointing to the directory with your project's manage.py file within it. If for example you cloned a repository called tango_with_django19 into your account's home directory, the path will be something like:

```
/home/<username>/tango_with_django_19/code/tango_with_django_project/
```

Configuring the WSGI Script

The Web Server Gateway Interface²²⁶, a.k.a. *WSGI* provides a simple and universal interface between Web servers and Web applications. PythonAnywhere uses WSGI to bridge the server-application link and map incoming requests to your subdomain to your web application.

To configure the WSGI script, navigate to the *Web* tab in PythonAnywhere's interface. Under the Code heading you can see a link to the WSGI configuration file in the Code section: e.g. /var/www/<username>_pythonanywhere_com_wsgi.py.

The people at PythonAnywhere have set up a sample WSGI file for us with several possible configurations. For your Web application, you'll need to configure the Django section of the file by clicking on the link to open a simple editor. The example below demonstrates a possible configuration for your application.

²²⁶http://en.wikipedia.org/wiki/Web_Server_Gateway_Interface

Ensure that you replace <username> with your PythonAnywhere username, and update any other path settings to suit your application. You should also remove all other code from the WSGI configuration script to ensure no conflicts take place.

The script adds your project's directory to the PYTHONPATH for the Python instance that runs your web application. This allows Python to access your project's modules. If you have additional paths to add, you can easily insert them here. You can then specify the location of your project's settings.py module. The final step is to include the Django WSGI handler and invoke it for your application.

When you have completed the WSGI configuration, click the *Save* button at the top-right of the webpage. Before we can (re)load the application, we need to set a few security parameters (see the Django Documentation for a Security Deployment Checklist²²⁷).

Allowing your Hostname

In Django, they have a security feature which will only except requests from particular, *allowed* hosts. By only allowing specified domains to be served by your web server, this reduces the chance that your app could be part HTTP Host Header attack²²⁸. If you were to load and view your application now, you would encounter a DisallowedHost exception stopping your app from loading.

This is a simple problem to fix, and involves a change in your project's settings.py module. First, work out your app's URL on PythonAnywhere. For a basic account, this will be http://<username>.pythonanywhere.com, where <username> is replaced with your PythonAnywhere username. It's a good idea to edit this file locally (on your own computer), then git add, git commit and git push your changes to your Git repository, before downloading the changes to your PythonAnywhere account. Alternatively, you can edit the file directly on PythonAnywhere by editing the file in the Web interface's files component – or using a text editor in the terminal, like nano or vi.

With this information, open your project's settings.py module and locate the ALLOWED_HOSTS list, which by default will be empty (and found near the top of the file). Add a string with your PythonAnywhere URL into that list – such that it now looks like the following example.

```
ALLOWED_HOSTS = ['http://<username>.pythonanywhere.com']
```

If you have edited the file on your own computer, you can now go through the (hopefully) now familiar process of running the git add settings.py, git commit and git push commands to make changes to your Git repository. Once done, you should then run the git pull command to retrieve the changes on your PythonAnywhere account. If you have edited the file directly on PythonAnywhere, simply save the file.

All that then remains is for you to reload your PythonAnywhere app. This can be done by clicking the *Reload* button in the PythonAnywhere web components page. Once you've done this, access

²²⁷https://docs.djangoproject.com/en/2.1/howto/deployment/checklist/

²²⁸ https://www.acunetix.com/blog/articles/automated-detection-of-host-header-attacks/

your app's URL, and you should see your app working, but without static media, which we will set up shortly.

Bad Gateway Errors

During deployment sometimes you might receive HTTP 502 - Bad Gateway errors instead of your application. Try reloading your application again, and then waiting a longer. If the problem persists, try reloading again. If the problem still persists, check out your log files to see if any accesses/errors are occurring, before contacting the PythonAnywhere support.

Setting the Secret Key

It is wise not to commit your secret key your git repository - and instead load in the key in. To do this, open your project's settings.py file and either chnage the secret key that you are using in production (hack) or load it from a file:

```
key = None
with open('/home/<username>/secret.key') as f:
    key = f.read().strip()
SECRET_KEY = key
```

Then create a file called secret.key and put it into your home directory.

Adding your Search API Key

While you are adding secret keys, also add your search API key²²⁹ to bing key so that the search functionality in Rango is enabled.

Turning off DEBUG Mode

Next you need to turn off the debug mode, because if you leave it on, then you are providing hackers with sensitive information about your web application when they get it to crash. So it is a good idea to instruct Django that your application is now hosted on a production server. To do this, open your project's settings.py file and change DEBUG = True to DEBUG = False. This disables Django's debug mode²³⁰, and removes explicit error messages. You can still however view Python stack traces to debug any exceptions that are raised as people use your app – in the server logs (see below).

 $^{{\}tt ^{229}} \ | \ cct\ char"007B \ relax \# section-searchapi-adding-key\ protect\ char"007D \ relax \# searchapi-adding-key\ protect\ char \ relax \# searchapi-adding-key\ protect\ char \ relax \# searchapi-adding-key\$

²³⁰https://docs.djangoproject.com/en/2.1/ref/settings/#debug

Assigning Static Paths

We're almost there. One issue that we still have to address is to sort out paths for our application. Doing so will allow PythonAnywhere's servers to serve your static content, for example From the PythonAnywhere dashboard, click the URL of your app and wait for the page to load.

Once loaded, perform the following under the *Static files* header. We essentially are adding in the correct URLs and filesystem paths to allow PythonAnywhere's web server to find and serve your static media files.

First, we should set the location of the Django admin interface's static media files. Click the *Enter URL* link, and type in /static/admin/. Click the tick to confirm your input, and then click the *Enter path* link, entering the following long-winded filesystem path (all on a single line).

```
/home/<username>/.virtualenvs/rango/lib/<python-version>/site-packages/django/
contrib/admin/static/admin
```

As usual, replace <username> with your PythonAnywhere username. <python-version> should also be replaced with python2.7, python3.6, etc., depending on which Python version you selected. You may also need to change rango if this is not the name of your application's virtual environment. Remember to hit return to confirm the path, or click the tick.

Repeat the two steps above for the URL/static/ and filesystem path/home/<username>/<path-to>/tango_-with_django_project/static, with the path setting pointing to the static directory of your Web application.

Setting the admin static directory means that when you visit the admin interface, it has the predefined Django stylesheets, while the applications static directory means your application has access to the images and scripts.

Enabling HTTPS

Not to make sure that your site is serving requests securely we can enable the HTTPS functionality provided by PythonAnywhere. They will vouch for your application, and provide a security certificate to say your application is from a secure site, and the HTTPS protocol will encrypt the requests. To do this, scroll down on the web apps tab and click the enable on the Force HTTPS button. You will notice that you can even add a password to protect your site when it is under development. Once you have set the HTTPS setting, you will need re-load your application.

Now go to the top of the web app dashboard and reload your Web application. Visit your website, and hopefully everything should load up nicely... and relatively securely.

Log Files

Deploying your Web application to an online environment introduces another layer of complexity. It is likely that you will encounter new and bizarre errors due to unsuspecting problems. When

facing such errors, vital clues may be found in one of the three log files that the Web server on PythonAnywhere creates.

Log files can be viewed via the PythonAnywhere web interface by clicking on the *Web* tab, or by viewing the files in /var/log/ within a Bash console instance. The files provided are:

- access.log, which provides a log of requests made to your subdomain;
- error.log, which logs any error messages produced by your web application; and
- server.log, providing log details for the UNIX processes running your application.

Note that the names for each log file are prepended with your subdomain. For example, access.log will have the name <username>.pythonanywhere.com.access.log.

When debugging, you may find it useful to delete or move the log files so that you don't have to scroll through a huge list of previous attempts. If the files are moved or deleted, they will be recreated automatically when a new request or error arises.

Exercises

Congratulations, you've successfully deployed Rango!

- Go through the Django's Security Deployment Checklist²³¹ and configure your application to be more secure.
- Tweet a link of your application to @tangowithdjango²³².
- Tweet or e-mail us to let us know your thoughts on the tutorial!

²³¹https://docs.djangoproject.com/en/2.1/howto/deployment/checklist/

²³²https://twitter.com/tangowithdjango

Final Thoughts

In this book, we have gone through the process of web development from specification to deployment. Along the way we have shown how to use the Django framework to construct the models, views and templates associated with a Web application. We have also demonstrated how toolkits and services like Bootstrap, JQuery and PythonAnywhere. can be integrated within an application. However, the road doesn't stop here. While, as we have only painted the broad brush strokes of a web application - as you have probably noticed there are lots of improvements that could be made to Rango - and these finer details often take a lot more time to complete as you polish the application. By developing your application on a firm base and good setup you will be able to construct up to 80% of your site very rapidly and get a working demo online.

In future versions of this book we intend to provide some more details on various aspects of the framework, along with covering the basics of some of the other fundamental technologies associated with web development. If you have any suggestions or comments about how to improve the book please get in touch.

Please report any bugs, problems, etc., or submit change requests via GitHub²³³. Thank you!

Acknowledgements

This book was written to help teach web application development to computing science students. In writing the book and the tutorial, we have had to rely upon the awesome Django community and the Django Documentation for the answers and solutions. This book is really the combination of that knowledge pieced together in the context of building Rango.

We would also like to thank all the people who have helped to improve this resource by sending us comments, suggestions, Git issues and pull requests. If you've sent in changes over the years, please do remind us if you are not on the list!

Appendices

This supplementary chapter provides additional setup guides that complement the initial setup chapter. We provide setup guides for installing and configuring the various technologies that you will be using within Tango with Django. Refer to the section that is relevant to you; you do not need to work through all of this chapter if things are already working for you.

Common Guides

This chapter provides instructions on how to set up the various technologies that you'll be using throughout Tango with Django that we believe will work on the largest number of systems. However, every computer setup is different, with different versions of software installed. These differences make providing universal setup guides very difficult to do.

If you are using this book as part of a course, you may be provided with setup instructions unique to your lab computers. Follow these instructions instead – a majority of the setup work will likely be taken care of for you already.

However, if you are working solo and you follow the instructions provided in this chapter without success, we recommend heading to your favourite search engine and entering the problem you're having. Typically, this will involve copying and pasting the error message you see at whatever step you're struggling at. By pasting in the message verbatim, chances are you'll find someone who suffered the same issue as you – and from that point, you'll hopefully find a solution to resolve your problem.

Installing Python 3 and pip

How do you go about installing Python 3.7 on your computer? This section answers that question. As we discussed previously, you may find that you already have Python installed on your computer. If you are using a Linux distribution or macOS, you will definitely have it installed. Some of your operating system's functionality is implemented in Python²⁷⁷, hence the need for an interpreter! Unfortunately, most modern operating systems that come preloaded with Python use a version that is much older than what we require. Exceptions include Ubuntu, coming with version 3.6.5 which should be sufficient for your needs. If you do need to install 3.7, we must install this version of Python side-by-side with the old one.

There's many different ways in which you can install Python. We demonstrate here the most common approaches that you can use on Apple's macOS, various Linux distributions and Windows 10. Pick the section associated with your operating system to proceed. Note that we favour the use

²⁷⁷http://en.wikipedia.org/wiki/Yellowdog_Updater,_Modified

of package managers²⁷⁸ where appropriate to ensure that you have the means of maintaining and updating the software easily (when required).

Apple macOS

The simplest way to acquire Python 3 for macOS is to download a .dmg image file from the official Python website²⁷⁹. This will provide you with a step-by-step installation interface that makes setting everything up straightforward. If your development environment will be kept lightweight (i.e. Python only), this option makes sense. Simply download the installer, and Python 3 should then be available on your Mac's terminal!

However, package managers make life easier²⁸⁰ when development steps up and involves a greater number of software tools. Installing a package manager makes it easy to maintain and update software on your computer – and even to install new software, too. macOS does not come preinstalled with a package manager, so you need to download and install one yourself. If you want to go down this route, we'll introduce you to *MacPorts*, a superb package manager offering a large host of tools²⁸¹ for you to download and use. We recommend that you follow this route. Although more complex, the end result will be a complete development environment, ready for you to get coding.

A prerequisite for using MacPorts is that you have Apple's *Xcode* environment installed. This download is several gigabytes in size. The easiest way to acquire this is through the App Store on your macOS installation. You'll need your Apple account to download that software. Once XCode has been installed, follow the following steps to setup MacPorts.

- 1. Verify that XCode is installed by launching it. You should see a welcome screen. If you see this, quit the app.
- 2. Open a Terminal window. Install the XCode command line tools by entering the command

```
$ xcode-select --install
```

This will download additional software tools that will be required by XCode and additional development software that you later install.

3. Agree to the XCode license, if you have not already. You can do this by entering the command

```
$ xcode-build license
```

Read the terms to the bottom of the page, and type Y to complete – but only if you agree to the terms!

4. From the MacPorts installation page²⁸², download the MacPorts installer for your correct macOS version.

²⁷⁸https://en.wikipedia.org/wiki/Package_manager

²⁷⁹https://www.python.org/downloads/mac-osx/

 $^{{}^{280}} https://software engineering.stack exchange.com/questions/372444/why-prefer-a-package-manager-over-a-library-folder and the state of the$

²⁸¹https://www.macports.org/ports.php

²⁸²https://www.macports.org/install.php

5. On your Mac's Finder, open the directory where you downloaded the installer to, and double-click the file to launch the installation process.

- 6. Follow the steps, and provide your password to install the software.
- 7. Once complete, delete the installer file you no longer require it. Close down any Terminal windows that are still open.

Once the MacPorts installation has been completed, installing Python is straightforward.

- 1. Open a new Terminal window. It is important that you launch a new window after MacPorts installation!
- 2. Enter the command

```
$ sudo port install python37
```

After entering your password, this will take a few minutes. Several dependencies will be required – agree to these being installed by responding with Y.

3. Once installation completes, activate your new Python installation. Enter the command

```
$ sudo port select --set python python37
```

4. Test that the command succeeds by issuing the command \$ python. You should then see the interpreter for Python 3.7.2 (or whatever version you just installed).

Once this has been completed, Python has been successfully installed and is ready to use. However, we still need to setup virtual environments to work with your installation.

1. Enter the following commands to install virtualenv and helper functions provided in the user-friendly wrapper.

```
$ sudo port install py37-virtualenv
$ sudo port install py37-virtualenvwrapper
```

2. Activate py37-virtualenv with the following command.

```
$ sudo port select --set virtualenv virtualenv37
```

3. Edit your \sim /.profile file. Add the following four lines at the end of the file.

```
export VIRTUALENVWRAPPER_PYTHON='/opt/local/bin/python3.7'
export VIRTUALENVWRAPPER_VIRTUALENV='/opt/local/bin/virtualenv-3.7'
export VIRTUALENVWRAPPER_VIRTUALENV_CLONE='/opt/local/bin/virtualenv-clone-3.7'
source /opt/local/bin/virtualenvwrapper.sh-3.7
```

4. Save the file and close all open Terminals. Open a new Terminal. Everything should now be working and ready for you to use.

Installating Additional Software with MacPorts

MacPorts provides an extensive, preconfigured library of open-source software suited specifically for development environments. When you need something new, it's a cinch to install. For example, you want to install the *LaTeX* typesetting system, search the MacPorts ports list²⁸³ – the resultant package name being texlive-latex. This could then be installed with the command \$ sudo port install texlive-latex. All software that LaTeX is dependent upon is also installed. This saves you significant amounts of time trying to find all the right bits of software to make things work.

To view the packages MacPorts has already installed on your system, issue the command \$ port list installed. You will see python37 listed!

Linux Distributions

There are many different ways in which you can download, install and run an updated version of Python on your Linux distribution. Methodologies unfortunately vary from distribution to distribution. To compound this, almost all distributions of Linux don't have a precompiled version of Python 3.7 ready for you to download and start using (at the time of writing), although the latest release of Ubuntu use Python 3.6 (which is sufficient).

If you do choose to install a new version of Python, we've put together a series of steps that you can follow. These will allow you to install Python 3.7.2 from scratch. The steps have been tested thoroughly in Ubuntu 18.04 LTS; other distributions should also work with minor tweaks, especially in relation to the package manager being used in step 1. A cursory search on your favorite search engine should reveal the correct command to enter. For example, on a *Red Hat Enterprise Linux* installation, the system package manager is yum instead of apt.

Assumption of Knowledge

In order to complete these steps, we assume you know the basics for Bash interaction, including what the tilde (\sim) means, for example. Be careful with the sudo command, and do not execute it except for the steps we list requiring it below.

1. Install the required packages for Python to be built successfully. These are listed below, line by line. These can be entered into an Ubuntu Terminal as-is; slight modifications will be required for other Linux distributions.

²⁸³https://www.macports.org/ports.php

```
$ apt install wget
$ apt install build-essential
$ apt install libssl-dev
$ apt install libffi-dev
$ apt install python-dev
$ apt install zlib1g-dev
$ apt install libbz2-dev
$ apt install libreadline-dev
$ apt install libsqlite3-dev
```

2. Once the above packages are installed, download the source for Python 3.7.2. We create a pytemp directory to download the file to. We'll delete this once everything has completed.

```
$ mkdir ~/pytemp
$ cd ~/pytemp
$ wget https://www.python.org/ftp/python/3.7.2/Python-3.7.2.tgz
```

3. Extract the .tgz file.

```
$ tar zxf Python-3.7.2.tgz
$ cd Python-3.7.2
```

4. Configure the Python source code for your computer, and build it. altinstall tells the installer to install the new version of Python to a different directory from the prexisting version of Python on your computer. You'll need to enter your password for the system to make the necessary changes. This process will take a few minutes, and you'll see a lot of output. Don't panic. This is normal. If the build fails, you haven't installed all of the necessary prerequisites. Check you have installed everything correctly from step 1, and try again.

```
$ sudo ./configure --enable-optimizations
$ sudo make altinstall
```

5. Once complete, delete the source files. You don't need them anymore.

```
$ cd ~
$ rm -rf ~/pytemp
```

6. Attempt to run the new installation of Python. You should see the interpreter prompt for version 3.7.2, as expected.

```
$ python3.7
Python 3.7.2 (default, Jan. 8 2019, 20:05:08)
[GCC 7.3.0] on linux
Type "help", "copyright", "credits" or "license" for more information
>>> quit()
$
```

7. By default, Python executables install to /usr/local/bin. Check this is correct for you. If not, run the which command to find out where it is installed. You'll need this path later.

```
$ which python3.7
/usr/local/bin/python3.7
```

8. Install virtualenv and virtualenvwrapper for your new Python installation.

```
$ pip3.7 install virtualenv
$ pip3.7 install virtualenvwrapper
```

9. Modify your ~/.bashrc file, and include the following lines at the very bottom of the file. Note that if you are not using Ubuntu, you might need to edit ~/.profile instead. Check the documentation of your distribution for more information. A simple text editor will allow you to do this, like nano.

```
EXPORT VIRTUALENVWRAPPER_PYTHON=/usr/local/bin/python3.7 source /usr/local/bin/virtualenvwrapper.sh
```

10. Restart your Terminal. Python 3.7.2 will now be setup and ready for you to use, along with the pip and virtualenv tools.

Windows

By default, Microsoft Windows comes with no installation of Python. This means that you do not have to worry about leaving existing installations alone; installing from scratch should work just fine. You can download a 64-bit of 32-bit version of Python from the official Python website²⁸⁴. If you aren't sure what one to download, you can determine if your computer is 32-bit or 64-bit by looking at the instructions provided on the Microsoft website²⁸⁵.

- 1. Download the appropriate installer from the official Python website²⁸⁶. At the time of writing, the latest release was version 3.7.2.
- 2. Run the installer. You'll want to make sure that you check the box saying that Python 3.7 is added to PATH. You'll want to install for all users, too. Choose the Customize option.
- 3. Proceed with the currently selected check boxes, and choose Next.

²⁸⁴http://www.python.org/download/

²⁸⁵https://support.microsoft.com/en-gb/help/13443/windows-which-operating-system

²⁸⁶http://www.python.org/download/

4. Make sure that the check box for installing Python for all users is checked. The installation location will change. Refer to the figure below for an example.

- 5. Click Next to install Python. You will need to give the installer elevated privileges to install the software.
- 6. Close the installer when completed, and delete the file you downloaded you no longer require it.

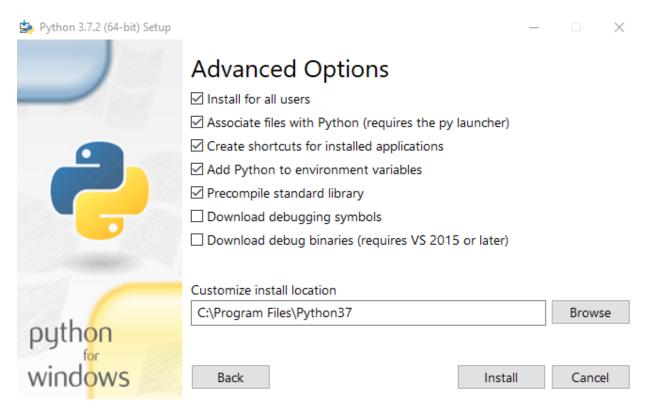

Once the installer is complete, you should have a working version of Python 3.7 installed and ready to go. Following the instructions above, Python 3.7 is installed to the directory C:\Program Files\Python37. If you checked all of the options correctly, the PATH environment variable used by Windows should also have been updated to incorporate the new installation of Python. To test this, launch a Command Prompt window and type \$ python. Execute the command. You should see the Python interpreter launch, as demonstrated in the screenshot below. If this fails, check your PATH environment variable is set correctly by following an online guide²⁸⁷.

Once you are sure that Python is installed correctly, you need to install virtual environment support. Issue the following two commands, and then restart all open Command Prompt windows.

```
$ pip install virtualenv
$ pip install virtualenvwrapper-win
```

Once completed, everything should be set up and ready for you to use.

²⁸⁷https://www.architectryan.com/2018/03/17/add-to-the-path-on-windows-10/

Configuring Python 3.7.2 on Windows 10 x64 – allowing the installation to be run by all users.

Virtual Environments

By default, when you install software for Python, it is installed *system-wide*. All Python applications can see the new software and make use of it. However, issues can occur with this setup. Earlier in the book, we discussed a scenario of two pieces of software requiring two different versions of the *same dependency*. This presents a headache; you cannot typically install two differing versions of the same software into your Python environment!

The solution to this is to use a *virtual environment*. Using a virtual environment, each different piece of software that you wish to run can be given its own environment, and by definition, its own set of installed dependencies. If you have ProjectA requiring Django 1.11 and ProjectB requiring Django 2.1, you could create a virtual environment for each with their own packages installed.

The four basic commands one would use to manipulate virtual environments are listed below.

- mkvirtualenv <name> creates and activates a new virtual environment of name <name>.
- workon <name> switches on a virtual environment of name <name>.
- deactivate switches off a virtual environment you are currently using.
- rmvirtualenv <name> deletes a virtual environment of name <name>.
- Isvirtualenv lists all user-created virtual environments.

Following the examples above, we can then create an environment for each, installing the required software in the relevant environment. For ProjectA, the environment is called projAENV, with projBENV used for ProjectB. Note that to install software to the respective environments, we use pip. The commands used for pip are discussed below.

```
$ mkvirtualenv projAENV
(projAENV) $ pip install Django==1.11
(projAENV) $ pip freeze
Django==1.11

(projAENV) $ deactive
$ pip
<Command not found>

$ workon projAENV
$ pip freeze
Django=1.11

(projAENV) $ cd ProjectA/
(projAENV) $ python manage.py runserver
...
```

The code blocks above create the new virtual environment, projAENV. We then install Django 1.11 to that virtual environment, before issuing pip freeze to list the installed packages – confirming that Django was installed. We then deactivate the virtual environment. pip then cannot be found as we are no longer in the virtual environment! By switching the virtual environment back on with workon, our Django package can once again be found. The final two commands launch the Django development server for ProjectA.

We can then create a secondary virtual environment, projBENV.

```
$ mkvirtualenv projBENV
(projBENV) $ pip install Django==2.1
(projBENV) $ pip freeze
Django==2.1

(projBENV) $ cd ProjectA/
(projBENV) $ python manage.py runserver
<INCORRECT PYTHON VERSION!>

(projBENV) $ workon projAENV
(projAENV) $ python manage.py runserver
```

```
(projAENV) $ workon projBENV
(projBENV) $ cd ProjectB/
$ python manage.py runserver
...
```

We create our new environment with the mkvirtualenv command. This creates and activates projBENV. However, when trying to launch the code for ProjectA, we get an error! We are using the wrong virtual environment. By switching to projAENV with workon projAENV, we can then launch the software correctly. This demonstrates the power of virtual environments, and the advantages that they can bring. Further tutorials can be found online.²⁸⁸

workon and deactivate

Start your session by switching on your virtual environment with the workon command. Finish your session by closing it with deactivate.

You can tell if a virtual environment is active by the brackets before your prompt, like (envname) \$. This means that virtual environment envname is currently switched on, with its settings loaded. Turn it off with deactivate and the brackets will disappear.

Multiple Python Versions

If you have multiple versions of Python installed, you can choose what version of Python to use when you create a virtual environment. If you have installations for python (which launches 2.7.15) and python3 (which launches 3.7.2), you can issue the following command to create a Python 3 virtual environment.

```
$ mkvirtualenv -p python3 someenv
$ python
$ Python 3.7.2
>>>
```

Note that when you enable your virtual environment, the command you enter to start Python is simply python. The same is applied for pip – if you launch pip3 outside a virtual environment, pip will be the command you use inside the virtual environment.

Using pip

The Python package manager is very straightforward to use, and allows you to keep track of the various Python packages (software) that you have installed. We highly recommend that you use pip

²⁸⁸https://realpython.com/python-virtual-environments-a-primer/

alongside a virtual environment, as packages installed using pip appear only within the said virtual environment.

When you find a package that you want to install, the command required is \$ pip install <packagename>==<version>. Note that the version component is optional; omitting the version of a particular package will meant that the latest available version is installed.

You can find the name of a package by examining the *PyPi package index*²⁸⁹, from which pip downloads software. Simply search or browse the index to find what you are looking for. Once you know the package's name, you can issue the installation command in your Terminal or Command Prompt.

pip is also super useful for listing packages that are installed in your environment. This can be achieved through the pip freeze command. Sample output is issued below.

```
(rangoenv) $ pip freeze
Django==2.1.5
Pillow==5.0.0
pytz==2018.9
```

This shows that three packages are installed in a given environment: Django, Pillow and pytz. The output from this command is typically saved to a file called requirements.txt, stored in the root directory of a Python project. If somebody wants to use your software, they can then download your software – complete with the requirements.txt file. Using this file, they can then create a new virtual environment set up with the required packages to make the software work.

If you find yourself in a situation like this, you runpip with the -r switch. Given a requirements.txt in a directory downloaded_project with only pytz==2018.9 listed, an example CLI session would therefore involve something like the following.

```
$ cd downloaded_project
$ mkvirtualenv someenv
(someenv) $ pip install -r requirements.txt
...
(someenv) $ pip freeze
pytz==2018.9
```

pip install installs packages from requirements.txt, and pip freeze, once everything has been installed, demonstrates that the packages have been installed correctly.

²⁸⁹https://pypi.org/

Version Control System

When developing code, it's highly recommended that you house your codebase within a version controlled respository such as SVN²⁹⁰ or Git²⁹¹. We have provided a chapter on how to use Git if you haven't used Git and GitHub before. We highly recommend that you set up a Git repository for your own projects. Doing so could save you from disaster.

To use Git, we recommend that you use the command-line tool to interact with your repositories. This is done through the git command. On Windows, you'll need to download Git from the Git website²⁹². If using macOS or Linux, the Git website also has downloadable installers for you to use²⁹³. However, why not get into the habit of using a package manager to install the software? This is generally the recommended way for downloading and using software developed on the UNIX design principles (including macOS).

For example, installing Git is as simple as typing \$ sudo apt install git. Let the software download, and the apt package manager takes care of the rest. If you installed MacPorts on your macOS installation as described above, Git will already be present for you as it is part of the Apple XCode Command Line Developer Tools.

Once installed, typing git will show the commands you can use, as shown in the example below.

A Crash Course in UNIX-based Commands

Depending on your computing background, you may or may not have encountered a UNIX based system, or a derivative of. This small crash course focuses on getting you up to speed with the *terminal*, an application in which you issue commands for the computer to execute. This differs from a point-and-click *Graphical User Interface (GUI)*, the kind of interface that has made computing so much more accessible. A terminal based interface may be more complex to use, but the benefits of using such an interface include getting things done quicker, and more accurately, too.

Not for Windows!

Note that we're focusing on the Bash shell, a shell for UNIX-based operating systems and their derivatives, including OS X and Linux distributions. If you're a Windows user, you can use the Windows Command Prompt²⁹⁴ or Windows PowerShell²⁹⁵. Users of Windows 10 with the 2016 Anniversary Update²⁹⁶ will also be able to issue Bash commands directly to the Command Prompt²⁹⁷. You could also experiment by installing Cygwin²⁹⁸ to bring Bash commands to Windows.

Using the Terminal

UNIX based operating systems and derivatives - such as OS X and Linux distributions - all use a similar looking terminal application, typically using the Bash shell²⁹⁹. All possess a core set of commands that allow you to navigate through your computer's filesystem and launch programs - all without the need for any graphical interface.

Upon launching a new terminal instance, you'll be typically presented with something resembling the following.

sibu:~ david\$

What you see is the *prompt*, and indicates when the system is waiting to execute your every command. The prompt you see varies depending on the operating system you are using, but all look generally very similar. In the example above, there are three key pieces of information to observe:

²⁹⁴http://www.ai.uga.edu/mc/winforunix.html

²⁹⁵https://msdn.microsoft.com/en-us/powershell/mt173057.aspx

²⁹⁶https://blogs.windows.com/windowsexperience/2016/08/02/how-to-get-the-windows-10-anniversary-update/

²⁹⁷http://www.pcworld.com/article/3050473/windows/heres-how-windows-10s-ubuntu-based-bash-shell-will-actually-work.html

²⁹⁸https://www.cygwin.com/

²⁹⁹https://en.wikipedia.org/wiki/Bash_(Unix_shell)

- your username and computer name (username of david and computer name of sibu);
- your *present working directory* (the tilde, or \sim); and
- the privilege of your user account (the dollar sign, or \$).

What is a Directory?

In the text above, we refer to your present working directory. But what exactly is a *directory*? If you have used a Windows computer up until now, you'll probably know a directory as a *folder*. The concept of a folder is analogous to a directory - it is a cataloguing structure that contains references to other files and directories.

The dollar sign (\$) typically indicates that the user is a standard user account. Conversely, a hash symbol (#) may be used to signify the user logged in has root privileges³⁰⁰. Whatever symbol is present is used to signify that the computer is awaiting your input.

Prompts can Differ

The information presented by the prompt on your computer may differ from the example shown above. For example, some prompts may display the current date and time, or any other information. It all depends how your computer is set up.

When you are using the terminal, it is important to know where you are in the file system. To find out where you are, you can issue the command pwd. This will display your *Present Working Directory* (hence pwd). For example, check the example terminal interactions below.

Last login: Wed Mar 23 15:01:39 2016 sibu:~ david\$ pwd /users/grad/david sibu:~ david\$

You can see that the present working directory in this example is /users/grad/david.

You'll also note that the prompt indicates that the present working directory is a tilde \sim . The tilde is used a special symbol which represents your *home directory*. The base directory in any UNIX based file system is the *root directory*. The path of the root directory is denoted by a single forward slash (/). As folders (or directories) are separated in UNIX paths with a /, a single / denotes the root!

If you are not in your home directory, you can *Change Directory* (cd) by issuing the following command:

³⁰⁰http://en.wikipedia.org/wiki/Superuser

```
sibu:/ david$ cd ~
sibu:~ david$
```

Note how the present working directory switches from / to \sim upon issuing the cd \sim command.

Path Shortcuts

UNIX shells have a number of different shorthand ways for you to move around your computer's filesystem. You've already seen that a forward slash (/) represents the root directory³⁰¹, and the tilde (\sim) represents your home directory in which you store all your personal files. However, there are a few more special characters you can use to move around your filesystem in conjunction with the cd command.

- Issuing cd ~ will always return you to your home directory. On some UNIX or UNIX derivatives, simply issuing cd will return you to your home directory, too.
- Issuing cd .. will move your present working directory **up one level** of the filesystem hierarchy. For example, if you are currently in /users/grad/david/code/, issuing cd .. will move you to /users/grad/david/.
- Issuing cd will move you to the **previous directory you were working in**. Your shell remembers where you were, so if you were in /var/tmp/ and moved to /users/grad/david/, issuing cd will move you straight back to /var/tmp/. This command obviously only works if you've move around at least once in a given terminal session.

Now, let's create a directory within the home directory called code. To do this, you can use the *Make Directory* command, called mkdir.

```
sibu:~ david$ mkdir code
sibu:~ david$
```

There's no confirmation that the command succeeded. We can change the present working directory with the cd command to change to code. If this succeeds, we will know the directory has been successfully created.

```
sibu:~ david$ cd code
sibu:code david$
```

Issuing a subsequent pwd command to confirm our present working directory yields /users/grad/david/code - our home directory, with code appended to the end. You can also see from the prompt in the example above that the present working directory changes from \sim to code.

³⁰¹https://en.wikipedia.org/wiki/Root_directory

Change Back

Now issue the command to change back to your home directory. What command do you enter?

From your home directory, let's now try out another command to see what files and directories exist. This new command is called 1s, shorthand for *list*. Issuing 1s in your home directory will yield something similar to the following.

```
sibu:~ david$ ls
code
```

This shows us that there's something present our home directory called code, as we would expect. We can obtain more detailed information by adding a 1 switch to the end of the 1s command - with 1 standing for *list*.

```
sibu:~ david$ ls -l
drwxr-xr-x 2 david grad 68 2 Apr 11:07 code
```

This provides us with additional information, such as the modification date (2 Apr 11:07), whom the file belongs to (user david of group grad), the size of the entry (68 bytes), and the file permissions (drwxr-xr-x). While we don't go into file permissions here, the key thing to note is the d at the start of the string that denotes the entry is a directory. If we then add some files to our home directory and reissue the 1s -1 command, we then can observe differences in the way files are displayed as opposed to directories.

One final useful switch to the 1s command is the a switch, which displays *all* files and directories. This is useful because some directories and files can be *hidden* by the operating system to keep things looking tidy. Issuing the command yields more files and directories!

```
sibu:~ david$ ls -la
-rw-r--r--
            1 david
                      grad
                                463 20 Feb 19:58 .profile
drwxr-xr-x
            16 david
                                544 25 Mar 11:39 .virtualenvs
                      grad
                                    2 Apr 11:07 code
drwxr-xr-x
            2 david
                       grad
-rw-r--r-@ 1
                                     1 Apr 16:16 document.pdf
               david
                       grad
                             303844
-rw-r--r--
                                     2 Apr 11:14 readme.md
               david
                      grad
```

This command shows a hidden directory .virtualenvs and a hidden file .profile. Note that hidden files on a UNIX based computer (or derivative) start with a period (.). There's no special hidden file attribute you can apply, unlike on Windows computers.

Combining 1s Switches

You may have noticed that we combined the 1 and a switches in the above 1s example to force the command to output a list displaying all hidden files. This is a valid command - and there are even more switches you can use³⁰² to customise the output of 1s.

Creating files is also easy to do, straight from the terminal. The touch command creates a new, blank file. If we wish to create a file called new.txt, issue touch new.txt. If we then list our directory, we then see the file added.

```
sibu:~ david$ ls -l
drwxr-xr-x 2 david grad 68 2 Apr 11:07 code
-rw-r--r-@ 1 david grad 303844 1 Apr 16:16 document.pdf
-rw-r--r-- 1 david grad 0 2 Apr 11:35 new.txt
-rw-r--r-- 1 david grad 14 2 Apr 11:14 readme.md
```

Note the filesize of new.txt - it is zero bytes, indicating an empty file. We can start editing the file using one of the many available text editors that are available for use directly from a terminal, such as nano³⁰³ or vi³⁰⁴. While we don't cover how to use these editors here, you can have a look online for a simple how-to tutorial³⁰⁵. We suggest starting with nano - while there are not as many features available compared to other editors, using nano is much simpler.

Core Commands

In the short tutorial above, you've covered a few of the core commands such as pwd, 1s and cd. There are however a few more standard UNIX commands that you should familiarise yourself with before you start working for real. These are listed below for your reference, with most of them focusing upon file management. The list comes with an explanation of each, and an example of how to use them.

³⁰²http://man7.org/linux/man-pages/man1/ls.1.html

³⁰³http://www.nano-editor.org/

³⁰⁴http://en.wikipedia.org/wiki/Vi

³⁰⁵http://www.howtogeek.com/howto/42980/the-beginners-guide-to-nano-the-linux-command-line-text-editor/

- pwd: As explained previously, this command displays your *present working directory* to the terminal. The full path of where you are presently is displayed.
- 1s: Displays a list of files in the current working directory to the terminal.
- cd: In conjunction with a path, cd allows you to change your present working directory. For example, the command cd /users/grad/david/ changes the current working directory to /users/grad/david/. You can also move up a directory level without having to provide the absolute path³⁰⁶ by using two dots, e.g. cd ...
- cp: Copies files and/or directories. You must provide the *source* and the *target*. For example, to make a copy of the file input.py in the same directory, you could issue the command cp input_backup.py.
- mv: Moves files/directories. Like cp, you must provide the *source* and *target*. This command is also used to rename files. For example, to rename numbers.txt to letters.txt, issue the command mv numbers.txt letters.txt. To move a file to a different directory, you would supply either an absolute or relative path as part of the target like mv numbers.txt /home/david/numbers.txt.
- mkdir: Creates a directory in your current working directory. You need to supply a name for the
 new directory after the mkdir command. For example, if your current working directory was
 /home/david/ and you ran mkdir music, you would then have a directory /home/david/music/.
 You will need to then cd into the newly created directory to access it.
- rm: Shorthand for *remove*, this command removes or deletes files from your filesystem. You must supply the filename(s) you wish to remove. Upon issuing a rm command, you will be prompted if you wish to delete the file(s) selected. You can also remove directories using the recursive switch³⁰⁷. Be careful with this command recovering deleted files is very difficult, if not impossible!
- rmdir: An alternative command to remove directories from your filesystem. Provide a directory
 that you wish to remove. Again, be careful: you will not be prompted to confirm your
 intentions.
- sudo: A program which allows you to run commands with the security privileges of another user. Typically, the program is used to run other programs as root the superuser³⁰⁸ of any UNIX-based or UNIX-derived operating system.

There's More!

This is only a brief list of commands. Check out Ubuntu's documentation on Using the Terminal³⁰⁹ for a more detailed overview, or the Cheat Sheet³¹⁰ by FOSSwire for a quick, handy reference guide. Like anything else, the more you practice, the more comfortable you will feel working with the terminal.

³⁰⁶ http://www.coffeecup.com/help/articles/absolute-vs-relative-pathslinks/

³⁰⁸http://en.wikipedia.org/wiki/Superuser

³⁰⁹https://help.ubuntu.com/community/UsingTheTerminal

http://fosswire.com/post/2007/08/unixlinux-command-cheat-sheet/

We strongly recommend that you spend some time familiarising yourself with a version control³¹¹ system for your application's codebase. This chapter provides you with a crash course in how to use Git³¹², one of the many version control systems available. Originally developed by Linus Torvalds³¹³, Git is today one of the most popular version control systems in use³¹⁴, and is used by open-source and closed-source projects alike.

This tutorial demonstrates at a high level how Git works, explains the basic commands that you can use, and provides an explanation of Git's workflow. By the end of this chapter, you'll be able to make contributions to a Git repository, enabling you to work solo, or in a team.

Why Use Version Control?

As your software engineering skills develop, you will find that you are able to plan and implement solutions to ever more complex problems. As a rule of thumb, the larger the problem specification, the more code you have to write. The more code you write, the greater the emphasis you should put on software engineering practices. Such practices include the use of design patterns and the *DRY* (*Don't Repeat Yourself*) principle.

Think about your experiences with programming thus far. Have you ever found yourself in any of these scenarios?

- Made a mistake to code, realised it was a mistake and wanted to go back?
- Lost code (through a faulty drive), or had a backup that was too old?
- Had to maintain multiple versions of a product (perhaps for different organisations)?
- Wanted to see the difference between two (or more) versions of your codebase?
- Wanted to show that a particular change broke of fixed a piece of code?
- Wanted to submit a change (patch) to someone else's code?
- Wanted to see how much work is being done (where it was done, when it was done, or who did it)?

Using a version control system makes your life easier in *all* of the above cases. While using version control systems at the beginning may seem like a hassle it will pay off later - so it's good to get into the habit now!

³¹¹https://en.wikipedia.org/wiki/Version_control

³¹²http://en.wikipedia.org/wiki/Git_(software)

³¹³http://en.wikipedia.org/wiki/Linus_Torvalds

³¹⁴https://en.wikipedia.org/wiki/Comparison_of_source_code_hosting_facilities#Popularity

We missed one final (and important) argument for using version control. With ever more complex problems to solve, your software projects will undoubtedly contain a large number of files containing source code. It'll also be likely that you *aren't working alone on the project; your project will probably have more than one contributor.* In this scenario, it can become difficult to avoid conflicts when working on files.

How Git Works

Essentially, Git comprises of four separate storage locations: your workspace, the local index, the local repository and the remote repository. As the name may suggest, the remote repository is stored on some remote server, and is the only location stored on a computer other than your own. This means that there are two copies of the repository - your local copy, and the remote copy. Having two copies is one of the main selling points of Git over other version control systems. You can make changes to your local repository when you may not have Internet access, and then apply any changes to the remote repository at a later stage. Only once changes are made to the remote repository can other contributors see your changes.

What is a Repository?

We keep repeating the word *repository*, but what do we actually mean by that? When considering version control, a repository is a data structure which contains metadata (a set of data that describes other data, hence *meta*) concerning the files which you are storing within the version control system. The kind of metadata that is stored can include aspects such as the historical changes that have taken place within a given file, so that you have a record of all changes that take place.

If you want to learn more about the metadata stored by Git, there is a technical tutorial available ³¹⁵ for you to read through.

For now though, let's provide an overview of each of the different aspects of the Git system. We'll recap some of the things we've already mentioned just to make sure it makes sense to you.

• As already explained, the **remote repository** is the copy of your project's repository stored on some remote server. This is particularly important for Git projects that have more than one contributor - you require a central place to store all the work that your team members produce. You could set up a Git server on a computer with Internet access and a properly configured firewall (check out this Server Fault question³¹⁶, for example), or simply use one of many services providing free Git repositories. One of the most widely used services available today is GitHub³¹⁷. In fact, this book has a Git repository³¹⁸ on GitHub!

³¹⁵http://www.sbf5.com/~cduan/technical/git/git-1.shtml

 $^{^{316}} http://server fault.com/questions/189070/what-firewall-ports-need-to-be-open-to-allow-access-to-external-git-repositories and the server fault. ³¹⁷https://github.com/

³¹⁸https://github.com/leifos/tango_with_django_19

• The **local repository** is a copy of the remote repository stored on your computer (locally). This is the repository to which you make all your additions, changes and deletions. When you reach a particular milestone, you can then *push* all your local changes to the remote repository. From there, you can instruct your team members to retrieve your changes. This concept is known as *pulling* from the remote repository. We'll subsequently explain pushing and pulling in a bit more detail.

- The **local index** is technically part of the local repository. The local index stores a list of files that you want to be managed with version control. This is explained in more detail later in this chapter. You can have a look here³¹⁹ to see a discussion on what exactly a Git index contains.
- The final aspect of Git is your **workspace**. Think of this folder or directory as the place on your computer where you make changes to your version controlled files. From within your workspace, you can add new files or modify or remove previously existing ones. From there, you then instruct Git to update the repositories to reflect the changes you make in your workspace. This is important don't modify code inside the local repository you only ever edit files in your workspace.

Next, we'll be looking at how to get your Git workspace set up and ready to go. We'll also discuss the basic workflow you should use when using Git.

Setting up Git

We assume that you've got Git installed with the software to go. One easy way to test the software out is to simply issue git to your terminal or Command Prompt. If you don't see a command not found error, you're good to go. Otherwise, have a look at how to install Git to your system.

Using Git on Windows

Like Python, Git doesn't come as part of a standard Windows installation. However, Windows implementations of the version control system can be downloaded and installed. You can download the official Windows Git client from the Git website³²⁰. The installer provides the git command line program, which we use in this crash course. You can also download a program called *TortoiseGit*, a graphical extension to the Windows Explorer shell. The program provides a really nice right-click Git context menu for files. This makes version control really easy to use. You can download TortoiseGit³²¹ for free. Although we do not cover how to use TortoiseGit in this crash course, many tutorials exist online for it. Check this tutorial³²² if you are interested in using it.

We recommend however that you stick to the command line program. We'll be using the commands in this crash course. Furthermore, if you switch to a UNIX/Linux development environment at a later stage, you'll be glad you know the commands!

³¹⁹ http://stackoverflow.com/questions/4084921/what-does-the-git-index-exactly-contains

³²⁰http://git-scm.com/download/win

³²¹https://code.google.com/p/tortoisegit/

³²²²http://robertgreiner.com/2010/02/getting-started-with-git-and-tortoisegit-on-windows/

Setting up your Git workspace is a straightforward process. Once everything is set up, you will begin to make sense of the directory structure that Git uses. Assume that you have signed up for a new account on GitHub³²³ and created a new repository on the service³²⁴ for your project. With your remote repository setup, follow these steps to get your local repository and workspace setup on your computer. We'll assume you will be working from your \text{workspace} \text{ directory}.

- 1. Open a terminal and navigate to your home directory (e.g. \$ cd \sim).
- 2. *Clone* the remote repository or in other words, make a copy of it. Check out how to do this below.
- 3. Navigate into the newly created directory. That's your workspace in which you can add files to be version controlled!

How to Clone a Remote Repository

Cloning your repository is a straightforward process with the git clone command. Supplement this command with the URL of your remote repository - and if required, authentication details, too. The URL of your repository varies depending on the provider you use. If you are unsure of the URL to enter, it may be worth querying it with your search engine or asking someone in the know.

For GitHub, try the following command, replacing the parts below as appropriate:

```
$ git clone https://<USER>:<PASS>@github.com/<OWNER>/<REPO_NAME>.git <workspace>
```

where you replace

- <USER> with your GitHub username;
- <PASS> with your GitHub password;
- <OWNER> with the username of the person who owns the repository;
- <REPO_NAME> with the name of your project's repository; and
- <workspace> with the name for your workspace directory. This is optional; leaving this option out will simply create a directory with the same name as the repository.

If all is successful, you'll see some text like the example shown below.

³²³https://github.com/

 $^{^{324}} https://help.github.com/articles/create-a-repo$

```
$ git clone https://github.com/leifos/tango_with_django_19
Cloning into 'tango_with_django_19'...
remote: Counting objects: 18964, done.
remote: Total 18964 (delta 0), reused 0 (delta 0), pack-reused 18964
Receiving objects: 100% (18964/18964), 99.69 MiB | 3.51 MiB/s, done.
Resolving deltas: 100% (13400/13400), done.
Checking connectivity... done.
```

If the output lines end with done, everything should have worked. Check your filesystem to see if the directory has been created.

Not using GitHub?

There are many websites that provide Git repositories - some free, some paid. While this chapter uses GitHub, you are free to use whatever service you wish. Other providers include Atlassian Bitbucket³²⁵ and Unfuddle³²⁶. You will of course have to change the URL from which you clone your repository if you use a service other than GitHub.

The Directory Structure

Once you have cloned your remote repository onto your local computer, navigate into the directory with your terminal, Command Prompt or GUI file browser. If you have cloned an empty repository the workspace directory should appear empty. This directory is therefore your blank workspace with which you can begin to add your project's files.

However, the directory isn't blank at all! On closer inspection, you will notice a hidden directory called .git. Stored within this directory are both the local repository and local index. **Do not alter the contents of the .git directory**. Doing so could damage your Git setup and break version control functionality. Your newly created workspace therefore actually contains within it the local repository and index.

Final Tweaks

With your workspace setup, now would be a good time to make some final tweaks. Here, we discuss two cool features you can try which could make your life (and your team members') a little bit easier.

When using your Git repository as part of a team, any changes you make will be associated with the username you use to access your remote Git repository. However, you can also specify your full name and e-mail address to be included with changes that are made by you on the remote repository. Simply open a Command Prompt or terminal and navigate to your workspace. From there, issue two commands: one to tell Git your full name, and the other to tell Git your e-mail address.

³²⁵https://bitbucket.org/

³²⁶https://unfuddle.com/

```
$ git config user.name "John Doe"
$ git config user.email "johndoe123@me.com"
```

Obviously, replace the example name and e-mail address with your own - unless your name actually is John Doe.

Git also provides you with the capability to stop - or ignore - particular files from being added to version control. For example, you may not wish a file containing unique keys to access web services from being added to version control. If the file were to be added to the remote repository, anyone could theoretically access the file by cloning the repository. With Git, files can be ignored by including them in the <code>.gitignore</code> file, which resides in the root of <code>workspace</code>. When adding files to version control, Git parses this file. If a file that is being added to version control is listed within <code>.gitignore</code>, the file is ignored. Each line of <code>.gitignore</code> should be a separate file entry.

Check out the following example of a .gitignore file:

```
`config/api_keys.py`
`*.pyc`
```

In this example file, there are two entries - one on each line. The first entry prompts Git to ignore the file <code>api_keys.py</code> residing within the <code>config</code> directory of your repository. The second entry then prompts Git to ignore *all* instance of files with a <code>.pyc</code> extension, or compiled Python files. This is a really nice feature: you can use <code>wildcards</code> to make generic entries if you need to!

.gitignore - What else should I ignore?

There are many kinds of files you could safely ignore from being committed and pushed to your Git repositories. Examples include temporary files, databases (that can easily be recreated) and operating system-specific files. Operating system-specific files include configurations for the appearance of the directory when viewed in a given file browser. Windows computers create thumbs.db files, while OS X creates .DS_Store files.

When you create a new repository on GitHub, the service can offer to create a .gitignore file based upon the languages you will use in your project, which can save you some time setting everything up.

Basic Commands and Workflow

With your repository cloned and ready to go on your local computer, you're ready to get to grips with the Git workflow. This section shows you the basic Git workflow - and the associated Git commands you can issue.

A Figure of the Git Workflow

We have provided a pictorial representation of the basic Git workflow as shown above. Match each of the numbers in the black circles to the numbered descriptions below to read more about each stage. Refer to this diagram whenever you're unsure about the next step you should take - it's very useful!

1. Starting Off

Before you can start work on your project, you must prepare Git. If you haven't yet sorted out your project's Git workspace, you'll need to clone your repository to set it up.

If you've already cloned your repository, it's good practice to get into the habit of updating your local copy by using the git pull command. This *pulls* the latest changes from the remote repository onto your computer. By doing this, you'll be working from the same page as your team members. This will reduce the possibility of conflicting versions of files, which really does make your life a bit of a nightmare.

To perform a git pull, first navigate to your directory within your Command Prompt
 or terminal, then issue git pull. Check out the snippet below from a Bash terminal to see exactly
 what you need to do, and what output you should expect to see.

```
$ cd <workspace>
$ git pull
remote: Counting objects: 3, done.
remote: Compressing objects: 100% (2/2), done.
remote: Total 3 (delta 0), reused 0 (delta 0), pack-reused 0
Unpacking objects: 100% (3/3), done.
From https://github.com/someuser/somerepository
    86a0b3b..a7cec3d master -> origin/master
Updating 86a0b3b..a7cec3d
Fast-forward
    README.md | 1 +
    1 file changed, 1 insertion(+)
    create mode 100644 README.md
```

This example shows that a README.md file has been updated or created from the latest pull.

Getting an Error?

If you receive fatal: Not a git repository (or any of the parent directories): .git, you're not in the correct directory. You need cd to your workspace directory - the one in which you cloned your repository to. A majority of Git commands only work when you're in a Git repository.

Pull before you Push!

Always git pull on your local copy of your repository before you begin to work. Always! Before you are about to push, do another pull.

Remember to talk to your team to coordinate your activity so you are not working on the same files, or using branching.

2. Doing Some Work!

Once your workspace has been cloned or updated with the latest changes, it's time for you to get some work done! Within your workspace directory, you can take existing files and modify them. You can delete them too, or add new files to be version controlled.

When you modify your repository in any way, you need to keep Git up-to-date of any changes. Doing so allows Git to update your local index. The list of files stored within the local index are then used to perform your next *commit*, which we'll be discussing in the next step. To keep Git informed, there are several Git commands that let you update the local index. Three of the commands are near identical to those that were discussed in the Unix Crash Course (e.g. cp, mv), with the addition of a git prefix.

- The first command git add allows you to request Git to add a particular file to the next commit for you. A common newcomer mistake is to assume that git add is used for adding new files to your repository only this is not the case. You must tell Git what modified files you wish to commit, too. The command is invoked by typing git add <filename>, where <filename> is the name of the file you wish to add to your next commit. Multiple files and directories can be added with the command git add . but be careful with this³²⁷.
- git mv performs the same function as the Unix mv command it moves files. The only difference between the two is that git mv updates the local index for you before moving the file. Specify the filename with the syntax git mv <current_filename> <new_filename>. For example, with this command you can move files to a different directory within your repository. This will be reflected in your next commit. The command is also used to rename files from the old filename to the new.

³²⁷http://stackoverflow.com/a/16969786

• git cp allows you to make a copy of a file or directory while adding references to the new files into the local index for you. The syntax is the same as git mv above where the filename or directory name is specified thus: git cp <current_filename> <copied_filename>.

• The command git rm adds a file or directory delete request into the local index. While the git rm command does not delete the file straight away, the requested file or directory is removed from your filesystem and the Git repository upon the next commit. The syntax is similar to the git add command, where a filename can be specified thus: git rm <filename>. Note that you can add a large number of requests to your local index in one go, rather than removing each file manually. For example, git rm -rf media/ creates delete requests in your local index for the media/ directory. The r switch enables Git to recursively remove each file within the media/ directory, while f allows Git to forcibly remove the files. Check out the Wikipedia page³²⁸ on the rm command for more information.

Lots of changes between commits can make things pretty confusing. You may easily forget what files you've already instructed Git to remove, for example. Fortunately, you can run the git status command to see a list of files which have been modified from your current working directory, but haven't been added to the local index for processing. Check out typical output from the command below to get a taste of what you can see.

Working with .gitignore

If you have set up your <code>.gitignore</code> file correctly, you'll notice that files matching those specified within the <code>.gitignore</code> file are...ignored when you git <code>add</code> them. This is the intended behaviour - these files are not supposed to be committed to version control! If you however do need a file to be included that is in <code>.gitignore</code>, you can <code>force</code> Git to include it if necessary with the <code>git add -f <filename></code> command.

```
$ git status
On branch master
Your branch is up-to-date with 'origin/master'.
Changes to be committed:
   (use "git reset HEAD <file>..." to unstage)
      modified: chapter-unix.md
Changes not staged for commit:
   (use "git add <file>..." to update what will be committed)
   (use "git checkout -- <file>..." to discard changes in working directory)
      modified: chapter-git.md
```

From this example above, we can see that the file chapter-unix.md has been added to the latest commit, and will therefore be updated in the next git push. The file chapter-git.md has been updated, but git add hasn't been run on the file, so the changes won't be applied to the repository.

³²⁸http://en.wikipedia.org/wiki/Rm_(Unix)#Options

Checking Status

For further information on the git status command, check out the official Git documentation³²⁹.

3. Committing your Changes

We've mentioned *committing* several times in the previous step - but what does it mean? Committing is when you save changes - which are listed in the local index - that you have made within your workspace. The more often you commit, the greater the number of opportunities you'll have to revert back to an older version of your code if things go wrong. Make sure you commit often, but don't commit an incomplete or broken version of a particular module or function. There's a lot of discussion as to when the ideal time to commit is. Have a look at this Stack Overflow page³³⁰ for the opinions of several developers. It does however make sense to commit only when everything is working. If you find you need to roll back to a previous commit only to find nothing works, you won't be too happy.

To commit, you issue the git commit command. Any changes to existing files that you have indexed will be saved to version control at this point. Additionally, any files that you've requested to be copied, removed, moved or added to version control via the local index will be undertaken at this point. When you commit, you are updating the *HEAD* of your local repository³³¹.

Commit Requirements

In order to successfully commit, you need to modify at least one file in your repository and instruct Git to commit it, through the git add command. See the previous step for more information on how to do this.

As part of a commit, it's incredibly useful to your future self and others to explain why you committed when you did. You can supply an optional message with your commit if you wish to do so. Instead of simply issuing git commit, run the following amended command.

\$ git commit -m "Updated helpers.py to include a Unicode conversion function."

From the example above, you can see that using the -m switch followed by a string provides you with the opportunity to append a message to your commit. Be as explicit as you can, but don't write too much. People want to see at a glance what you did, and do not want to be bored or confused with a long essay. At the same time, don't be too vague. Simply specifying Updated helpers.py may tell a developer what file you modified, but they will require further investigation to see exactly what you changed.

³²⁹ http://git-scm.com/docs/git-status

 $^{^{330}} http://stackoverflow.com/questions/1480723/dvcs-how-often-and-when-to-commit-changes <math display="inline">^{331} http://stackoverflow.com/questions/2304087/what-is-git-head-exactly$

Sensible Commits

Although frequent commits may be a good thing, you will want to ensure that what you have written actually *works* before you commit. This may sound silly, but it's an incredibly easy thing to not think about. To reiterate, committing code which doesn't actually work can be infuriating to your team members if they then rollback to a version of your project's codebase which is broken!

4. Synchronising your Repository

Important when Collaborating

Synchronising your local repository before making changes is crucial to ensure you minimise the chance for conflicts occurring. Make sure you get into the habit of doing a pull before you push.

After you've committed your local repository and committed your changes, you're just about ready to send your commit(s) to the remote repository by *pushing* your changes. However, what if someone within your group pushes their changes before you do? This means your local repository will be out of sync with the remote repository, meaning that any git push command that you issue will fail.

It's therefore always a good idea to check whether changes have been made on the remote repository before updating it. Running a git pull command will pull down any changes from the remote repository, and attempt to place them within your local repository. If no changes have been made, you're clear to push your changes. If changes have been made and cannot be easily rectified, you'll need to do a little bit more work.

In scenarios such as this, you have the option to *merge* changes from the remote repository. After running the git pull command, a text editor will appear in which you can add a comment explaining why the merge is necessary. Upon saving the text document, Git will merge the changes from the remote repository to your local repository.

Editing Merge Logs

If you do see a text editor on your Mac or Linux installation, it's probably the vi ³³² text editor. If you've never used vi before, check out this helpful page containing a list of basic commands ³³³ on the Colorado State University Computer Science Department website. If you don't like vi, you can change the default text editor ³³⁴ that Git calls upon. Windows installations most likely will bring up Notepad.

³³²http://en.wikipedia.org/wiki/Vi

³³³http://www.cs.colostate.edu/helpdocs/vi.html

³³⁴http://git-scm.com/book/en/Customizing-Git-Git-Configuration#Basic-Client-Configuration

5. Pushing your Commit(s)

Pushing is the phrase used by Git to describe the sending of any changes in your local repository to the remote repository. This is the way in which your changes become available to your other team members, who can then retrieve them by running the git pull command in their respective local workspaces. The git push command isn't invoked as often as committing - *you require one or more commits to perform a push*. You could aim for one push per day, when a particular feature is completed, or at the request of a team member who is after your updated code.

To push your changes, the simplest command to run is:

\$ git push origin master

As explained on this Stack Overflow question and answer page³³⁵ this command instructs the git push command to push your local master branch (where your changes are saved) to the *origin* (the remote server from which you originally cloned). If you are using a more complex setup involving branching and merging³³⁶, alter master to the name of the branch you wish to push.

Important Push?

If your git push is particularly important, you can also alert other team members to the fact they should really update their local repositories by pulling your changes. You can do this through a *pull request*. Issue one after pushing your latest changes by invoking the command git request-pull master, where master is your branch name (this is the default value). If you are using a service such as GitHub, the web interface allows you to generate requests without the need to enter the command. Check out the official GitHub website's tutorial³³⁷ for more information.

Recovering from Mistakes

This section presents a solution to a coder's worst nightmare: what if you find that your code no longer works? Perhaps a refactoring went terribly wrong, or another team member without discussion changed something. Whatever the reason, using a form of version control always gives you a last resort: rolling back to a previous commit. This section details how to do just that. We follow the information given from this Stack Overflow³³⁸ question and answer page.

 $^{^{335}} http://stackoverflow.com/questions/7311995/what-is-git-push-origin-master-help-with-gits-refs-heads-and-remotes$

³³⁶http://git-scm.com/book/en/Git-Branching-Basic-Branching-and-Merging

 $^{^{337}} https://help.github.com/articles/using-pull-requests \\$

³³⁸http://stackoverflow.com/questions/2007662/rollback-to-an-old-commit-using-git

Changes may be Lost!

You should be aware that this guide will rollback your workspace to a previous iteration. Any uncommitted changes that you have made will be lost, with a very slim chance of recovery! Be wary. If you are having a problem with only one file, you could always view the different versions of the files for comparison. Have a look at this Stack Overflow page³³⁹ to see how to do that.

Rolling back your workspace to a previous commit involves two steps: determining which commit to roll back to, an performing the rollback. To determine what commit to rollback to, you can make use of the git log command. Issuing this command within your workspace directory will provide a list of recent commits that you made, your name and the date at which you made the commit. Additionally, the message that is stored with each commit is displayed. This is where it is highly beneficial to supply commit messages that provide enough information to explain what is going on. Check out the following output from a git log invocation below to see for yourself.

commit 88f41317640a2b62c2c63ca8d755feb9f17cf16e <- Commit hash Author: John Doe <someaddress@domain.com> <- Author Date: Mon Jul 8 19:56:21 2013 +0100 <- Date/time Nearly finished initial version of the requirements chapter <- Message commit f910b7d557bf09783b43647f02dd6519fa593b9f Author: John Doe <someaddress@domain.com> Date: Wed Jul 3 11:35:01 2013 +0100 Added in the Git figures to the requirements chapter. commit c97bb329259ee392767b87cfe7750ce3712a8bdf Author: John Doe <someaddress@domain.com> Tue Jul 2 10:45:29 2013 +0100 Date: Added initial copy of Sphinx documentation and tutorial code. commit 2952efa9a24dbf16a7f32679315473b66e3ae6ad Author: John Doe <someaddress@domain.com>

From this list, you can choose a commit to rollback to. For the selected commit, you must take the commit hash - the long string of letters and numbers. To demonstrate, the top (or HEAD) commit hash in the example output above is 88f41317640a2b62c2c63ca8d755feb9f17cf16e. You can select this in your terminal and copy it to your computer's clipboard.

With your commit hash selected, you can now rollback your workspace to the previous revision. You can do this with the git checkout command. The following example command would rollback to the commit with hash 88f41317640a2b62c2c63ca8d755feb9f17cf16e.

Initial commit

Mon Jul 1 03:56:53 2013 -0700

³³⁹http://stackoverflow.com/a/3338145

\$ git checkout 88f41317640a2b62c2c63ca8d755feb9f17cf16e .

Make sure that you run this command from the root of your workspace, and do not forget to include the dot at the end of the command! The dot indicates that you want to apply the changes to the entire workspace directory tree. After this has completed, you should then immediately commit with a message indicating that you performed a rollback. Push your changes and alert your collaborators - perhaps with a pull request. From there, you can start to recover from the mistake by putting your head down and getting on with your project.

Exercises

If you haven't undertaken what we've been discussing in this chapter already, you should go through everything now to ensure your Git repository is ready to go. To try everything out, you can create a new file README.md in the root of your <workspace> directory. The file will be used by GitHub³⁴⁰ to provide information on your project's GitHub homepage.

- Create the file, and write some introductory text to your project.
- Add the file to the local index upon completion of writing, and commit your changes.
- Push the new file to the remote repository and observe the changes on the GitHub website.

Once you have completed these basic steps, you can then go back and edit the readme file some more. Add, commit and push - and then try to revert to the initial version to see if it all works as expected.

There's More!

There are other more advanced features of Git that we have not covered in this chapter. Examples include **branching** and **merging**, which are useful for projects with different release versions, for example. There are many fantastic tutorials available online if you are interested in taking you super-awesome version control skills a step further. For more details about such features take a look at this tutorial on getting started with Git³⁴¹, the Git Guide³⁴² or Learning about Git Branching³⁴³.

However, if you're only using this chapter as a simple guide to getting to grips with Git, everything that we've covered should be enough. Good luck!

³⁴⁰ https://help.github.com/articles/github-flavored-markdown

 $^{^{341}} http://veeras undar.com/blog/2011/06/git-tutorial-getting-started/2011/06/git-started/2011/06/git$

³⁴²http://rogerdudler.github.io/git-guide/

³⁴³http://pcottle.github.io/learnGitBranching/

In Web development, we use *Cascading Style Sheets (CSS)* to describe the presentation of a HTML document (i.e. its look and feel).

Each element within a HTML document can be *styled*. The CSS for a given HTML element describes how it is to be rendered on screen. This is done by ascribing *values* to the different *properties* associated with an element. For example, the font-size property could be set to 24pt to make any text contained within the specified HTML element to appear at 24pt. We could also set the text-align property to a value of right to make text appear within the HTML element on the right-hand side.

CSS Properties

There are many, many different CSS properties that you can use in your stylesheets. Each provides a different functionality. Check out the W3C website³⁴⁴ and HTML Dog³⁴⁵ for lists of available properties. pageresource.com³⁴⁶ also has a neat list of properties, with descriptions of what each one does. Check out Section css-course-reading-label for a more comprehensive set of links.

CSS works by following a *select and apply pattern* - for a specified element, a set of styling properties are applied. Take a look at the following example in the figure below, where we have some HTML containing <h1> tags. In the CSS code example, we specify that all h1 be styled. We'll come back to selectors³⁴⁷ later on in this chapter. For now though, you can assume the CSS style defined will be applied to our <h1> tags. The style contains four properties:

- font-size, setting the size of the font to 16pt;
- font-style, which when set to italic italicises the contents of all <h1> tags within the document;
- text-align centres the text of the <h1> tags (when set to center); and
- color, which sets the colour of the text to red via hexadecimal code³⁴⁸ #FF0000.

With all of these properties applied, the resultant page render can be seen in the browser as shown in the figure below.

³⁴⁴http://www.w3.org/TR/CSS2/propidx.html

³⁴⁵http://www.htmldog.com/references/css/properties/

³⁴⁷http://www.w3schools.com/cssref/css_selectors.asp

³⁴⁸http://html-color-codes.com/

Illustration demonstrating the rendered output of the sample HTML markup and CSS stylesheet shown. Pay particular attention to the CSS example - the colours are used to demonstrate the syntax used to define styles and the property/value pairings associated with them.

What you see is what you (may or may not) get

Due to the nature of web development, what you see isn't necessarily what you'll get. This is because different browsers have their own way of interpreting web standards³⁴⁹ and so the pages may be rendered differently. This quirk can unfortunately lead to plenty of frustration, but today's modern browsers (or developers) are much more in agreement as to how different components of a page should be rendered.

Including Stylesheets

Including stylesheets in your webpages is a relatively straightforward process, and involves including a link> tag within your HTML's <head>. Check out the minimal HTML markup sample below for the attributes required within a link> tag.

As can be seen from above, there are at minimum three attributes that you must supply to the tag:

- rel, which allows you to specify the relationship between the HTML document and the resource you're linking to (i.e., a stylesheet);
- type, in which you should specify the MIME type³⁵⁰ for CSS; and
- href, the attribute which you should point to the URL of the stylesheet you wish to include.

³⁴⁹http://en.wikipedia.org/wiki/Web standards

³⁵⁰http://en.wikipedia.org/wiki/Internet_media_type

With this tag added, your stylesheet should be included with your HTML page, and the styles within the stylesheet applied. It should be noted that CSS stylesheets are considered as a form of static media, meaning you should place them within your project's static directory.

Inline CSS

You can also add CSS to your HTML documents *inline*, meaning that the CSS is included as part of your HTML page. However, this isn't generally advised because it removes the abstraction between presentational semantics (CSS) and content (HTML).

Basic CSS Selectors

CSS selectors are used to map particular styles to particular HTML elements. In essence, a CSS selector is a *pattern*. Here, we cover three basic forms of CSS selector: *element selectors*, *id selectors* and *class selectors*. Later on in this chapter, we also touch on what are known as *pseudo-selectors*.

Element Selectors

Taking the CSS example from the rendering example shown above, we can see that the selector ht matches to any <h1> tag. Any selector referencing a tag like this can be called an *element selector*. We can apply element selectors to any HTML element such as <body>, <h1>, <h2>, <h3>, and <div>. These can be all styled in a similar manner. However, using element selectors is pretty crude - styles are applied to *all* instances of a particular tag. We usually want a more fine-grained approach to selecting what elements we style, and this is where *id selectors* and *class selectors* come into play.

ID Selectors

The *id selector* is used to map to a unique element on your webpage. Each element on your webpage can be assigned a unique id via the id attribute, and it is this identifier that CSS uses to latch styles onto your element. This type of selector begins with a hash symbol (#), followed directly by the identifier of the element you wish to match to. Check out the figure below for an example

An illustration demonstrating the use of an *id selector* in CSS. Note the blue header has an identifier which matches the CSS attribute *blue_header.

Class Selectors

The alternative option is to use *class selectors*. This approach is similar to that of *id selectors*, with the difference that you can legitimately target multiple elements with the same class. If you have a group of HTML elements that you wish to apply the same style to, use a class-based approach. The selector for using this method is to precede the name of your class with a period (.) before opening up the style with curly braces ({ }). Check out the figure below for an example.

An illustration demonstrating the use of a *class selector* in CSS. The blue headers employ the use of the .blue CSS style to override the red text of the ht style.

Ensure ids are Unique

Try to use id selectors sparingly. Ask yourself:³⁵¹ *do I absolutely need to apply an identifier to this element in order to target it?* If you need to apply a given set of styles to more than one element, the answer will always be **no**. In cases like this, you should use a class or element selector.

Fonts

Due to the huge number available, using fonts has historically been a pitfall when it comes to web development. Picture this scenario: a web developer has installed and uses a particular font on his or her webpage. The font is pretty arcane - so the probability of the font being present on other computers is relatively small. A user who visits the developer's webpage subsequently sees the page rendered incorrectly as the font is not present on their system. CSS tackles this particular issue with the font-family property.

The value you specify for font-family can be a *list* of possible fonts - and the first one your computer or other device has installed is the font that is used to render the webpage. Text within the specified HTML element subsequently has the selected font applied. The example CSS shown below applies *Arial* if the font exists. If it doesn't, it looks for *Helvetica*. If that font doesn't exist, any available sans-serif font³⁵² is applied.

```
h1 {
    font-family: 'Arial', 'Helvetica', sans-serif;
}
```

In 1996, Microsoft started the core fonts for the Web³⁵³ initiative with the aim of guaranteeing a particular set of fonts to be present on all computers. Today however, you can use pretty much any

 $^{^{351}} http://net.tutsplus.com/tutorials/html-css-techniques/the-30-css-selectors-you-must-memorize/selectors-yo$

³⁵²http://en.wikipedia.org/wiki/Sans-serif

³⁵³http://en.wikipedia.org/wiki/Core_fonts_for_the_Web

font you like - check out Google Fonts³⁵⁴ for examples of the fonts that you can use and this Web Designer Depot article³⁵⁵ on how to use such fonts.

Colours and Backgrounds

Colours are important in defining the look and feel of your website. You can change the colour of any element within your webpage, ranging from background colours to borders and text. In this book, we make use of words and *hexadecimal colour codes* to choose the colours we want. As you can see from the list of basic colours shown in the figure below, you can supply either a *hexadecimal* or *RGB* (*red-green-blue*) value for the colour you want to use. You can also specify words to describe your colours³⁵⁶, such as green, yellow or blue.

Pick Colours Sensibly

Take great care when picking colours to use on your webpages. If you select colours that don't contrast well, people simply won't be to read your text! There are many websites available that can help you pick out a good colour scheme - try colorcombos.com³⁵⁷ for starters.

Applying colours to your elements is a straightforward process. The property that you use depends on the aspect of the element you wish to change! The following subsections explain the relevant properties and how to apply them.

Illustration of some basic colours with their corresponding hexadecimal and RGB values.

There are many different websites that you can use to aid you in picking the right hexadecimal codes to enter into your stylesheets. You aren't simply limited to the nine examples above! Try out httml-color-codes.com³⁵⁸ for a simple grid of colours and their associated six character hexadecimal code. You can also try sites such as color-hex.com³⁵⁹ which gives you fine grained control over the colours you can choose.

Hexadecimal Colour Codes

For more information on how colours are coded with hexadecimal, check out this thorough tutorial³⁶⁰.

Watch your English!

As you may have noticed, CSS uses American/International English to spell words. As such, there are a few words that are spelt slightly differently compared to their British counterparts, like color and center. If you have grown up in the United Kingdom, double check your spelling and be prepared to spell it the *wrong way!*

Text Colours

To change the colour of text within an element, you must apply the color property to the element containing the text you wish to change. The following CSS for example changes all the text within an element using class red to...red!

```
.red {
    color: #FF0000;
}
```

You can alter the presentation of a small portion of text within your webpage by wrapping the text within tags. Assign a class or unique identifier to the element, and from there you can simply reference the tag in your stylesheet while applying the color property.

Borders

You can change the colour of an element's *borders*, too. We'll discuss what borders are discussed as part of the CSS box model. For now, we'll show you how to apply colours to them to make everything look pretty.

Border colours can be specified with the border-color property. You can supply one colour for all four sides of your border, or specify a different colour for each side. To achieve this, you'll need to supply different colours, each separated by a space.

```
.some-element {
    border-color: #000000 #FF0000 #00FF00
}
```

In the example above, we use multiple colours to specify a different colour for three sides. Starting at the top, we rotate clockwise. Thus, the order of colours for each side would be top right bottom left.

Our example applies any element with class some-element with a black top border, a red right border and a green bottom border. No left border value is supplied, meaning that the left-hand border is left transparent. To specify a colour for only one side of an element's border, consider using the border-top-color, border-right-color, border-bottom-color and border-left-color properties where appropriate.

Background Colours

You can also change the colour of an element's background through use of the CSS background-color property. Like the color property described above, the background-color property can be easily applied by specifying a single colour as its value. Check out the example below which applies a bright green background to the entire webpage. Not very pretty!

```
body {
    background-color: #00FF00;
}
```

Background Images

Of course, a colour isn't the only way to change your backgrounds. You can also apply background images to your elements, too. We can achieve this through the background-image property.

```
#some-unique-element {
   background-image: url('../images/filename.png');
   background-color: #000000;
}
```

The example above makes use of filename.png as the background image for the element with identifier some-unique-element. The path to your image is specified *relative to the path of your CSS stylesheet*. Our example above uses the double dot notation to specify the relative path³⁶¹ to the image. *Don't provide an absolute path here; it won't work as you expect!* We also apply a black background colour to fill the gaps left by our background image - it may not fill the entire size of the element.

Background Image Positioning

By default, background images default to the top-left corner of the relevant element and are repeated on both the horizontal and vertical axes. You can customise this functionality by altering how the image is repeated³⁶² with the background-image property. You can also specify where the image is placed³⁶³ by default with the background-position property.

 $^{^{363}} http://www.w3schools.com/cssref/pr_background-position.asp$

Containers, Block-Level and Inline Elements

Throughout the crash course thus far, we've introduced you to the element but have neglected to tell you what it is. All will become clear in this section as we explain *inline* and *block-level* elements.

A is considered to be a so-called *container element*. Along with a <div> tag, these elements are themselves meaningless and are provided only for you to *contain* and *separate* your page's content in a logical manner. For example, you may use a <div> to contain markup related to a navigation bar, with another <div> to contain markup related to the footer of your webpage. As containers themselves are meaningless, styles are usually applied to help control the presentational semantics of your webpage.

Containers come in two flavours: *block-level elements* and *inline elements*. Check out the figure below for an illustration of the two kinds in action, and read on for a short description of each.

Diagram demonstrating how block-level elements and inline elements are rendered by default. With block-level elements as green, note how a line break is taken between each element. Conversely, inline elements can appear on the same line beside each other. You can also nest block-level and inline elements within each other, but block-level elements cannot be nested within an inline element.

Block-Level Elements

In simple terms, *block-level elements* are by default rectangular in shape and spread across the entire width of the containing element. Block-level elements therefore by default appear underneath each other. The rectangular structure of each block-level element is commonly referred to as the *box model*, which we discuss later on in this chapter. A typical block-level element you will use is the <div> tag, short for *division*.

Block-level elements can be nested within other block-level elements to create a hierarchy of elements. You can also nest *inline elements* within block-level elements, but not vice-versa! Read on to find out why.

Inline Elements

An *inline element* does exactly what it says on the tin. These elements appear *inline* to block-level elements on your webpage, and are commonly found to be wrapped around text. You'll find that tags are commonly used for this purpose.

This text-wrapping application was explained in the text colours section, where a portion of text could be wrapped in tags to change its colour. The corresponding HTML markup would look similar to the example below.

Refer back to the nested blocks figure above to refresh your mind about what you can and cannot nest before you move on.

Basic Positioning

An important concept that we have not yet covered in this CSS crash course regards the positioning of elements within your webpage. Most of the time, you'll be satisfied with inline elements appearing alongside each other, and block-level elements appearing underneath each other. These elements are said to be *positioned statically*.

However, there will be scenarios where you require a little bit more control on where everything goes. In this section, we'll briefly cover three important techniques for positioning elements within your webpage: *floats*, *relative positioning* and *absolute positioning*.

Floats

CSS *floats* are one of the most straightforward techniques for positioning elements within your webpage. Using floats allows us to position elements to the left or right of a particular container - or page.

Let's work through an example. Consider the following HTML markup and CSS code.

```
.red {
   background-color: red;
  border: 1px solid black;
}
```

This produces the output shown below.

We can see that each element follows its natural flow: the container element with class container spans the entire width of its parent container, while each of the <code>span</code> elements are enclosed inline within the parent. Now suppose that we wish to then move the red element with text <code>Span 2</code> to the right of its container. We can achieve this by modifying our CSS <code>.red</code> class to look like the following example.

```
.red {
   background-color: red;
  border: 1px solid black;
  float: right;
}
```

By applying the float: right; property and value pairing, we should then see something similar to the example shown below.

Note how the .red element now appears at the right of its parent container, .container. We have in effect disturbed the natural flow of our webpage by artificially moving an element! What if we then also applied float: left; to the .yellow ?

This would float the .yellow element, removing it from the natural flow of the webpage. In effect, it is not sitting on top of the .container container. This explains why the parent container does not now fill down with the elements like you would expect. You can apply the overflow: hidden; property to the parent container as shown below to fix this problem. For more information on how this trick works, have a look at this QuirksMode.org online article³⁶⁴.

³⁶⁴http://www.quirksmode.org/css/clearing.html

```
.container {
    border: 1px solid black;
    overflow: hidden;
}
```

Applying overflow: hidden ensures that our .container pushes down to the appropriate height.

Relative Positioning

Relative positioning can be used if you require a greater degree of control over where elements are positioned on your webpage. As the name may suggest to you, relative positioning allows you to position an element relative to where it would otherwise be located. We make use of relative positioning with the position: relative; property and value pairing. However, that's only part of the story.

Let's explain how this works. Consider our previous example where two elements are sitting within their container.

```
<div class="container">
    <span class="yellow">Span 1</span>
    <span class="red">Span 2</span>
</div>
.container {
    border: 1px solid black;
    height: 200px;
}
.yellow {
    background-color: yellow;
    border: 1px solid black;
}
.red {
    background-color: red;
    border: 1px solid black;
}
```

This produces the following result - just as we would expect. Note that we have artificially increased the height of our container element to 150 pixels. This will allow us more room with which to play with.

Now let's attempt to position our .red element relatively. First, we apply the position:
relative property and value pairing to our .red class, like so.

```
.red {
    background-color: red;
    border: 1px solid black;
    position: relative;
}
```

This has no effect on the positioning of our .red element. What it does do however is change the positioning of .red from static to relative. This paves the way for us to specify where - from the original position of our element - we now wish the element to be located.

```
.red {
    background-color: red;
    border: 1px solid black;
    position: relative;
    left: 150px;
    top: 80px;
}
```

By applying the left and top properties as shown in the example above, we are wanting the .red element to be *pushed* 150 pixels *from the left*. In other words, we move the element 150 pixels to the right. Think about that carefully! The top property indicates that the element should be pushed 80 pixels from the *top* of the element. The result of our experimentation can be seen below.

From this behaviour, we can see that the properties right and bottom *push* elements from the right and bottom respectively. We can test this out by applying the properties to our .yellow class as shown below.

```
.yellow {
   background-color: yellow;
   border: 1px solid black;
   float: right;
   position: relative;
   right: 10px;
   bottom: 10px;
}
```

This produces the following output. The .yellow container is pushed into the top left-hand corner of our container by pushing up and to the right.

Order Matters

What happens if you apply both a top and bottom property, or a left and right property? Interestingly, the *first* property for the relevant axis is applied. For example, if bottom is specified before top, the bottom property is used.

We can even apply relative positioning to elements that are floated. Consider our earlier example where the two <code></code> elements were positioned on either side of the container by floating <code>.red</code> to the right.

We can then alter the .red class to the following.

```
.red {
   background-color: red;
  border: 1px solid black;
  float: right;
  position: relative;
  right: 100px;
}
```

This means that relative positioning works from the position at which the element would have otherwise been at - regardless of any other position changing properties being applied.

Absolute Positioning

Our final positioning technique is *absolute positioning*. While we still modify the position parameter of a style, we use absolute as the value instead of relative. In contrast to relative positioning, absolute positioning places an element *relative to its first parent element that has a position value other than static.* This may sound a little bit confusing, but let's go through it step by step to figure out what exactly happens.

First, we can again take our earlier example of the two coloured elements within a <div> container. The two elements are placed side-by-side as they would naturally.

```
<div class="container">
    <span class="yellow">Span 1</span>
    <span class="red">Span 2</span>
</div>
.container {
   border: 1px solid black;
   height: 70px;
}
.yellow {
    background-color: yellow;
    border: 1px solid black;
}
.red {
    background-color: red;
    border: 1px solid black;
}
```

This produces the output shown below. Note that we again set our .container height to an artificial value of 70 pixels to give us more room.

We now apply absolute positioning to our .red element.

```
.red {
   background-color: red;
  border: 1px solid black;
  position: absolute;
}
```

Like with relative positioning, this has no overall effect on the positioning of our red element in the webpage. We must apply one or more of top, bottom, left or right in order for a new position to take effect. As a demonstration, we can apply top and left properties to our red element like in the example below.

```
.red {
   background-color: red;
  border: 1px solid black;
  position: absolute;
  top: 0;
  left: 0;
}
```

Wow, what happened here? Our red element is now positioned outside of our container! You'll note that if you run this code within your own web browser window, the red element appears in the top left-hand corner of the viewport. This therefore means that our top, bottom, left and right properties take on a slightly different meaning when absolute positioning is concerned.

As our container element's position is by default set to position: static, the red and yellow elements are moving to the top left and bottom right of our screen respectively. Let's now modify our .yellow class to move the yellow to 5 pixels from the bottom right-hand corner of our page. The .yellow class now looks like the example below.

```
.yellow {
    background-color: yellow;
    border: 1px solid black;
    position: absolute;
    bottom: 5px;
    right: 5px;
}
```

This produces the following result.

But what if we don't want our elements to be positioned absolutely in relation to the entire page? More often than not, we'll be looking to adjusting the positioning of our elements in relation to a container. If we recall our definition for absolute positioning, we will note that absolute positions are calculated *relative to the first parent element that has a position value other than static.* As our container is the only parent for our two <code></code> elements, the container to which the absolutely positioned elements is therefore the <code><body></code> of our HTML page. We can fix this by adding position: relative; to our <code>.container</code> class, just like in the example below.

```
.container {
   border: 1px solid black;
   height: 70px;
   position: relative;
}
```

This produces the following result. .container becomes the first parent element with a position value of anything other than relative, meaning our elements latch on!

Our elements are now absolutely positioned in relation to .container. Great! Now, let's adjust the positioning values of our two elements to move them around.

```
.yellow {
    background-color: yellow;
    border: 1px solid black;
    position: absolute;
    top: 20px;
    right: 100px;
}

.red {
    background-color: red;
    border: 1px solid black;
    position: absolute;
    float: right;
    bottom: 50px;
    left: 40px;
}
```

Note that we also apply float: right; to our .red element. This is to demonstrate that unlike relative positioning, absolute positioning *ignores any other positioning properties applied to an element*. top: 10px for example will always ensure that an element appears 10 pixels down from its parent (set with position: relative;), regardless of whether the element has been floated or not.

The Box Model

When using CSS, you're never too far away from using *padding*, *borders* and *margins*. These properties are some of the most fundamental styling techniques which you can apply to the elements within your webpages. They are incredibly important and are all related to what we call the *CSS box model*.

Each element that you create on a webpage can be considered as a box. The CSS box model³⁶⁵ is defined by the W3C³⁶⁶ as a formal means of describing the elements or boxes that you create, and how they are rendered in your web browser's viewport. Each element or box consists of *four separate* areas, all of which are illustrated in the figure below. The areas - listed from inside to outside - are the *content area*, the *padding area*, the *border area* and the *margin area*.

An illustration demonstrating the CSS box model, complete with key showing the four areas of the model.

For each element within a webpage, you can create a margin, apply some padding or a border with the respective properties margin, padding and border. Margins clear a transparent area around the border of your element; meaning margins are incredibly useful for creating a gap between elements. In contrast, padding creates a gap between the content of an element and its border. This therefore gives the impression that the element appears wider. If you supply a background colour for an element, the background colour is extended with the element's padding. Finally, borders are what you might expect them to be - they provide a border around your element's content and padding.

For more information on the CSS box model, check out addedbytes excellent explanation of the model³⁶⁷. Why not even order a t-shirt with the box model on it³⁶⁸?

³⁶⁵http://www.w3.org/TR/CSS2/box.html

³⁶⁶http://www.w3.org/

³⁶⁷ http://www.addedbytes.com/articles/for-beginners/the-box-model-for-beginners/

³⁶⁸http://cssboxmodel.com/

Watch out for the width!

As you may gather from the box model illustration, the width of an element isn't defined simply by the value you enter as the element's width. Rather, you should always consider the width of the border and padding on both sides of your element. This can be represented mathematically as:

```
total_width = content_width + left padding + right padding + left border + left
margin + right margin
```

Don't forget this. You'll save yourself a lot of trouble if you don't!

Styling Lists

Lists are everywhere. Whether you're reading a list of learning outcomes for a course or a reading a list of times for the train, you know what a list looks like and appreciate its simplicity. If you have a list of items on a webpage, why not use a HTML list? Using lists within your webpages - according to Brainstorm and Raves³⁶⁹ - promotes good HTML document structure, allowing text-based browsers, screen readers and other browsers that do not support CSS to render your page in a sensible manner.

Lists however don't look particularly appealing to end-users. Take the following HTML list that we'll be styling as we go along trying out different things.

Rendered without styling, the list looks pretty boring.

Let's make some modifications. First, let's get rid of the ugly bullet points. With our element already (and conveniently) set with class sample-list, we can create the following style.

```
.sample-list {
    list-style-type: none;
}
```

This produces the following result. Note the lack of bullet points!

³⁶⁹ http://brainstormsandraves.com/articles/semantics/structure/

Let's now change the orientation of our list. We can do this by altering the display property of each of our list's elements (<1i>). The following style maps to this for us.

```
.sample-list li {
    display: inline;
}
```

When applied, our list elements now appear on a single line, just like in the example below.

While we may have the correct orientation, our list now looks awful. Where does one element start and the other end? It's a complete mess! Let's adjust our list element style and add some contrast and padding to make things look nicer.

```
.example-list li {
    display: inline;
    background-color: #333333;
    color: #FFFFFF;
    padding: 10px;
}
```

When applied, our list looks so much better - and quite professional, too!

From the example, it is hopefully clear that lists can be easily customised to suit the requirements of your webpages. For more information and inspiration on how to style lists, you can check out some of the selected links below.

- Have a look at this excellent tutorial on styling lists on A List Apart³⁷⁰.
- Check out this advanced tutorial from Web Designer Wall³⁷¹ that uses graphics to make awesome looking lists. In the tutorial, the author uses Photoshop you could try using a simpler graphics package if you don't feel confident with Photoshop.
- This site³⁷² provides some great inspiration and tips on how you can style lists.

The possibilities of styling lists are endless! You could say it's a never-ending list...

³⁷⁰ http://alistapart.com/article/taminglists/

³⁷¹http://webdesignerwall.com/tutorials/advanced-css-menu

³⁷²http://learn.shayhowe.com/html-css/creating-lists/

Styling Links

CSS provides you with the ability to easily style hyperlinks in any way you wish. You can change their colour, their font or any other aspect that you wish - and you can even change how they look when you hover over them!

Hyperlinks are represented within a HTML page through the <a> tag, which is short for *anchor*. We can apply styling to all hyperlinks within your webpage as shown in following example.

```
a {
    color: red;
    text-decoration: none;
}
```

Every hyperlink's text colour is changed to red, with the default underline of the text removed. If we then want to change the color and text-decoration properties again when a user hovers over a link, we can create another style using the so-called pseudo-selector³⁷³:hover. Our two styles now look like the example below.

```
a {
    color: red;
    text-decoration: none;
}
a:hover {
    color: blue;
    text-decoration: underline;
}
```

This produces links as shown below. Notice the change in colour of the second link - it is being hovered over.

You may not however wish for the same link styles across the entire webpage. For example, your navigation bar may have a dark background while the rest of your page has a light background. This would necessitate having different link stylings for the two areas of your webpage. The example below demonstrates how you can apply different link styles by using a slightly more complex CSS style selector.

³⁷³http://css-tricks.com/pseudo-class-selectors/

```
#dark {
    background-color: black;
}
#dark a {
    color: white;
    text-decoration: underline;
}
#dark a:hover {
    color: aqua;
}
.light {
    background-color: white;
}
.light a {
    color: black;
    text-decoration: none;
}
.light a:hover {
    color: olive;
    text-decoration: underline;
}
```

We can then construct some simple markup to demonstrate these classes.

The resultant output looks similar to the example shown below. Code up the example above, and hover over the links in your browser to see the text colours change!

With a small amount of CSS, you can make some big changes in the way your webpages appear to users.

The Cascade

It's worth pointing out where the *Cascading* in *Cascading Style Sheets* comes into play. Looking back at the CSS rendering example way back at the start of this chapter, you will notice that the red text shown is **bold**, yet no such property is defined in our h1 style. This is a perfect example of what we mean by *cascading styles*. Most HTML elements have associated with them a *default style* which web browsers apply. For <h1> elements, the W3C website provides a typical style that is applied³⁷⁴. If you check the typical style, you'll notice that it contains a font-weight: bold; property and value pairing, explaining where the **bold** text comes from. As we define a further style for <h1> elements, typical property/value pairings *cascade* down into our style. If we define a new value for an existing property/value pairing (such as we do for font-size), we *override* the existing value. This process can be repeated many times - and the property/value pairings at the end of the process are applied to the relevant element. Check out the figure below for a graphical representation of the cascading process.

Illustration demonstrating the *cascading* in *Cascading Style Sheets* at work. Take note of the font-size property in our h1 style - it is overridden from the default value. The cascading styles produce the resultant style, shown on the right of the illustration.

Additional Reading

What we've discussed in this section is by no means a definitive guide to CSS. There are 300-page books³⁷⁵ devoted to CSS alone! What we have provided you with here is a very brief introduction showing you the very basics of what CSS is and how you can use it.

As you develop your web applications, you'll undoubtedly run into issues and frustrating problems with styling web content. This is part of the learning experience, and you still have a bit to learn. We strongly recommend that you invest some time trying out several online tutorials about CSS - there isn't really any need to buy a book (unless you want to).

• The *W3C* provides a neat tutorial on CSS³⁷⁶, taking you by the hand and guiding you through the different stages required. They also introduce you to several new HTML elements along the way, and show you how to style them accordingly.

 $^{^{374}}http://w3c.github.io/html-reference/h1.html\\$

³⁷⁵http://www.amazon.co.uk/Professional-CSS-Cascading-Sheets-Design/dp/047017708X

³⁷⁶http://www.w3.org/Style/Examples/011/firstcss.en.html

• W3Schools also provides some cool CSS tutorials³⁷⁷. Instead of guiding you through the process of creating a webpage with CSS, *W3Schools* has a series of mini-tutorials and code examples to show you to achieve a particular feature, such as setting a background image. We highly recommend that you have a look here.

• html.net has a series of lessons on CSS³⁷⁸ which you can work through. Like W3Schools, the tutorials on *html.net* are split into different parts, allowing you to jump into a particular part you may be stuck with.

This list is by no means exhaustive, and a quick web search will indeed yield much more about CSS for you to chew on. Just remember: CSS can be tricky to learn, and there may be times where you feel you want to throw your computer through the window. We say this is pretty normal - but take a break if you get to that stage. We'll be tackling some more advanced CSS stuff as we progress through the tutorial in the next few sections.

CSS And Browser Compatibility

With an increasing array of devices equipped with more and more powerful processors, we can make our web-based content do more. To keep up, CSS has constantly evolved³⁷⁹ to provide new and intuitive ways to express the presentational semantics of our SGML-based markup. To this end, support for relatively new CSS properties³⁸⁰ may be limited on several browsers, which can be a source of frustration. The only way to reliably ensure that your website works across a wide range of different browsers and platforms is to test, test and test some more!³⁸¹
